Extemporaneous Preparation of Troches—Troches are occasionally prescribed and may then be prepared advantageously by massing the material, rolling it into cylinder or "pill-pipe" and cutting into sections, approximately twice the length of the diameter. This readily provides uniformity in size and shape and is the most economic method for preparing troches extemporaneously. Prescription No. 32165, page 1817, illustrates this type. This shape of lozenge is known as a *bacillule*. Licorice lozenges are frequently of this type, and a popular lozenge of this shape was formerly known as Wister's lozenge.

CHAPTER CIV

TABLETS

Tabellæ—*Tablets*

This term in medicine and pharmacy is applied indiscriminately to a discoid or variously shaped form of medicine. These are further divided into several classes, determined by their method of manufacture or their use. These are described and discussed in the articles which follow.

Molded Tablets or Molded Tablet Triturates—Molded tablets, or tablet triturates, may be defined as small disk-like masses of medicinal powders, the basis usually consisting of powdered sugar of milk, or a mixture of sugar of milk and cane sugar. A tablet made from sugar of milk alone is too easily crushed so that usually a mixture consisting of sugar of milk, five parts, cane sugar, one part, is used. The powder is held together and the tablet retains its shape through the adhesion of the particles which is developed by the use of a volatile liquid like alcohol.

Tablet triturates originated with Dr. Robert M. Fuller, and neither process nor apparatus is patented. Since his first communication on the subject, in

Fig. 687

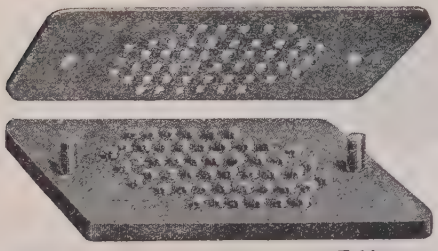

Fig. 688

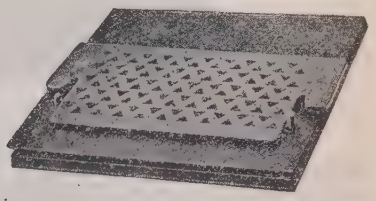


Tablet triturate machines

1878, they have been largely manufactured, and pharmacists owe a debt to Doctor Fuller for voluntarily giving them a very neat and ingenious process whereby many medicines can be satisfactorily administered.

The tablet is made by pressing a paste into perforations made in a plate of hard rubber, metal, or other suitable material. These holes are of uniform diameter, and the plate must have a uniform thickness throughout. The number of holes in the plate is determined by their relative size, plates having been made with as many as three hundred perforations. The tablets weigh from half a grain to four grains according to the plate used.

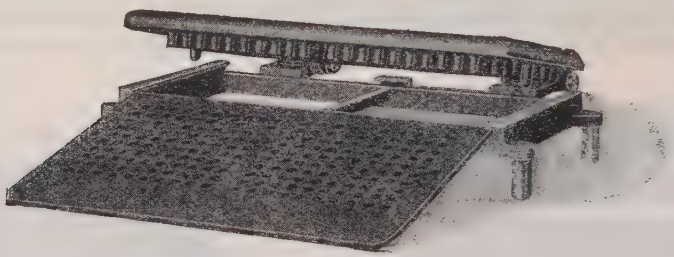
Preparation of Molded Tablets—In using the apparatus, the upper plate is placed upon a pill tile or plate of glass, and the paste is spread upon the upper surface and rubbed into the small holes with a spatula. When all of the holes are filled, the excess of paste is brushed from the surface, some of the dry triturate is dusted over both sides of the plate, and the latter set aside for a few minutes. The upper plate is then lifted over the lower plate and laid upon it so that the two long pegs enter the corresponding holes (see Fig. 687). Now, by pressing firmly but gently upon the upper plate the pegs are forced upward slowly until the plates come together and a tablet rests upon the

top of each peg; the apparatus is then set aside to permit the tablets to dry, when they are taken off, and the plates, after brushing, are ready for another operation. Fig. 688 shows another style of mold.

It will usually be found desirable to have several sets of plates, so that they may be worked continuously, the tablets drying upon one while another is being used for forming the tablets. The paste may be made by adding the medicating ingredient in fine powder to finely powdered sugar or sugar of milk and moistening it with alcohol or, in some instances, may be diluted with water containing a little syrup. Lactose or sugar of milk alone makes a tablet which is soft and easily crushed, but is the usual diluent used for molded hypodermic tablets. For other tablets it is customary, however, to employ as the diluent a mixture consisting of lactose or sugar of milk, five parts, cane sugar, one part. For oxidizable substances which are not intended to be dissolved, as for hypodermic use, kaolin or precipitated chalk have been used as diluents. In some rare cases a little powdered acacia may be needed, but care must be observed not to get the paste too tenacious nor too soft, as there may be difficulty in forcing the tablets out of the perforations, or they may take a long time to dry.

Tablets used for hypodermic medication may be advantageously made by

FIG. 689



Colton's No. 1 triturate machine

this process. Accurate adjustment of the ingredients and prolonged trituration, so that each tablet shall contain its due proportion of activity and thorough desiccation, are the important details in the manufacture of tablet triturates.

To avoid the development of mold on the tablets they must be thoroughly dried before bottling by spreading them on a frame covered with muslin, and exposing them to currents of warm air.

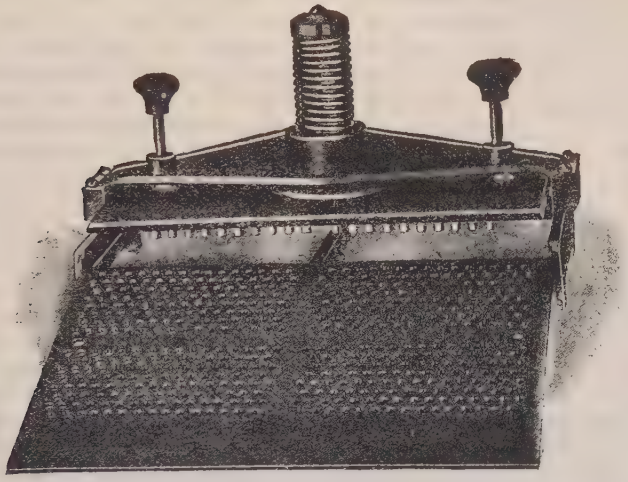
Developing a Formula—In developing a formula or deciding upon the amount of material required for a given number of tablets, the weight of the diluent which exactly fills all of the openings in the mold is determined by an experiment. This amount of diluent is then weighed and placed in a pile on the work counter, and by its side is placed the total amount of medication for the number of tablets made by the mold. A bulk of the diluent equal to the bulk of the medication is now withdrawn, the medication and remaining diluent are mixed by trituration and the resulting triturate moistened and forced into the openings in the molds. If they are not completely filled more diluent is added, its weight noted, and the formula then made up from the results of the experiment.

Figs. 689 and 690 show Colton's No. 1 and No. 2 triturate machines. Similar molds are made by the F. J. Stokes Company. Fig. 691 illustrates an automatic machine made by the Colton Company for the molding of tablets.

Many of the tablets sold today as tablet triturates are compressed on a

regular tablet machine (see page 699), being made in all respects like compressed tablets, excepting that the punches are made with flat faces to produce a tablet resembling the molded tablet. They, of course, represent the prin-

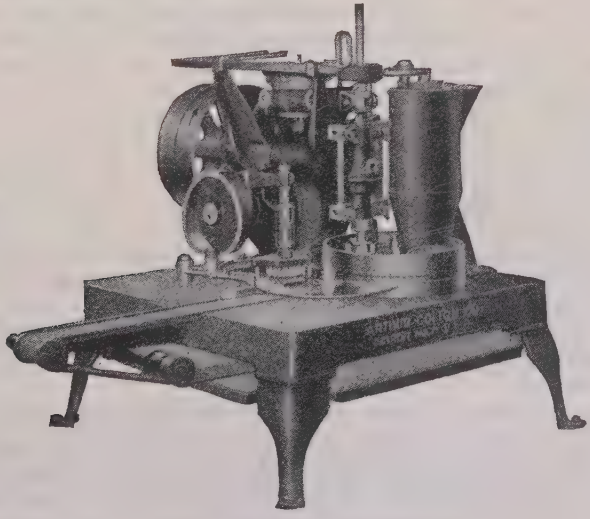
FIG. 690



Colton's No. 2 triturate machine

ciples of a triturate, *i.e.*, a small amount of medication and a diluent, uniformly mixed by trituration. It is less costly to make them on a compressing machine, if the apparatus is at hand, than by the molding process.

FIG. 691

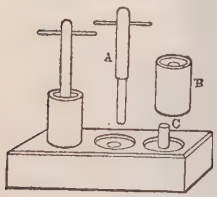


Colton's automatic triturate machine

Tablet triturates nave been made "in blank", that is, without medication. When medicating liquids have been added to them they are termed *tablet saturates*.

Compressed Pills, Troches, and Tablets—Compressed pills, troches, and tablets are forms of dosage medication, usually discoid in outline but also compressed into many other shapes to make them distinctive. They are made by subjecting dry, granular powders to a sufficient degree of pressure in suitable machines to cause them to cohere; the pressure may be effected by a blow from a mallet, or by means of a lever or combination of levers or, as is more usual, by automatic machines. To enable the pharmacist to prepare small quantities of his own compressed tablets, Joseph P. Remington devised, in 1875, the machine for making them shown in Fig. 692. It is made of cast steel. The base has two countersunk depressions, with a short post in the center of each; a lenticular depression is made in the upper surface of each post. A steel cylinder having a central aperture of the diameter of the post is placed in the depression, the proper quantity of powder is introduced, and the plunger, which has a corresponding lenticular depression on its lower surface, is placed on the powder and is struck a quick blow with a mallet; the powder is compressed, and the pill adheres to the cylinder; by removing the cylinder and holding it over a box and again tapping the plunger lightly, the pill is forced out, and falls into a box. While the molding of various forms of medication into tablets had been known for many years, William Brockedon, of England, was the first manufacturer to introduce this form of pill on a commercial scale. The records show that he was granted an English patent in 1843 for a machine to make pills and lozenges by pressure between dies. This machine, in principle, was much like the one illustrated in Fig. 662. In this country, Jacob Dunton, of Philadelphia, was the first to extend the process to a long line of pills, but subsequently John Wyeth and Brothers, and several others, prepared compressed pills and tablets upon an enormous scale, and they are made now by many manufacturers, both here and abroad. The tablets made by Burroughs, Wellcome and Company are known as *Tabloids*, which is a proprietary name and cannot be legally used by others.

Fig. 692



Hand tablet compressor

Preparation of Material—Most materials to be compressed require some simple treatment to insure proper operation of the tablet machine and a product of good appearance. Fine powder is objectionable for several reasons. First, it will not flow readily from the feeding device into the dies, producing wide variations in weight and density. Second, air is trapped in the tablets by the fine powder and causes the tablet to split or "cap". Third, the fine powder sifts down around the lower punches and blows up around the upper punches, necessitating frequent stops for cleaning the machine so that it will run properly.

Granulating—These faults are overcome by "granulating"—a process which changes the fine powder into small granules that are readily compressed into perfect tablets.

The general process of tablet making is practically the same in all cases, although details vary. The usual steps are pulverizing, sifting and mixing, granulating, drying, coarse grinding, lubricating, and flavoring. The finished granulation is then compressed. With some materials, one or more of these steps may be omitted. The machines used to perform these various operations will be discussed later.

There are a few materials which are already granular and need no treatment before compressing. Sodium bicarbonate in its commercial form is easily compressed into the so-called "soda mint tablets" if lubricated with 1 to

1.5 per cent of oil of peppermint before being run in the tablet machine. Other crystalline salts such as potassium chlorate, potassium permanganate, potassium nitrate and sodium, potassium, and ammonium chlorides, bromides, and iodides, also silver proteinate, methenamine, etc., need no treatment before compressing, other than sifting. Not all granular crystals will compress well. Granulated sugar is a familiar example of such material. The crystals are brittle and crack under pressure, producing broken and capped tablets; moreover, such material often sticks badly to the inside of the die. Tablets to be made from other substances than the few mentioned above or from combinations of several drugs and chemicals must be prepared in a granular form.

Many formulas for tablets call for not only chemical and vegetable drugs that merely have to be finely powdered and dried before mixing, but they very often call for tinctures, fluidextracts, volatile oils, hygroscopic materials, effervescent mixtures, and other ingredients that must be specially treated. A fluidextract or a tincture may be handled in several ways; it either may be concentrated to the consistence of a syrup and used as a moistening or granulating agent for the other ingredients, or it may be reduced to a solid extract, and, after being dried and powdered, added to the mixture. With oily extracts an absorbent is often necessary. For this purpose a substance such as magnesium carbonate is admirably adapted, 5 per cent of the weight of the extract usually sufficing. If the material is hygroscopic, dry starch or lactose added to the otherwise finished granulation after drying and just before compressing, will often counteract the effects of the moisture absorbed, if the material is not too hygroscopic. Some materials can be compressed successfully only on very dry days or in a room supplied with dehumidified air. If too much starch is added to the finished granulation, capped tablets may result. Volatile oils are added to the finished granulation immediately before compression. Under no circumstances should these volatile oils be added before drying. Materials which will react with organic bases may be mixed with inorganic substances such as talc or kaolin, if the material is not to be dissolved, or, if a soluble tablet is required, with dried and powdered sodium sulphate or magnesium sulphate. Mercuric chloride is usually diluted with an equal volume of sodium or ammonium chloride, which also greatly increases its solubility.

Diluents or Bases—Usually only a small percentage of a formula is active. The active ingredients are thoroughly mixed with inert substances called diluents or bases in order to increase the weight and size of the tablet. For this purpose powdered *sucrose* (cane sugar), *lactose* (milk sugar), corn starch, kaolin or mixtures of these materials, are used. Kaolin can be used to advantage as a base when mixed with corn starch and powdered sugar. In this mixture the starch acts as a disintegrator (see below), and the powdered sucrose as a "binder", so that an excellent tablet that will break down rapidly results. Sucrose may often be displaced as a base by a cheaper filler though it must be used in effervescing, alkaline, and antiseptic tablets, and in all tablets that should give a clear solution.

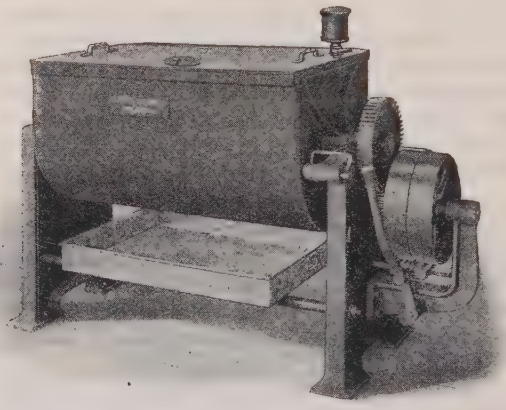
The various ingredients making up the formula should be thoroughly mixed and moistened with a granulating agent. Enough of the granulating solution is added to cause the fine particles to adhere, but not enough to form a damp mass. When only a small quantity of material is to be treated or when a poison or other very active ingredient is a part of the formula, the materials should be dampened and carefully triturated, using a mortar and pestle. In larger quantities the material is conveniently and efficiently handled in a granulating mixer as shown in Fig. 693. Water is the most common granu-

lating agent, either by itself or with a dissolved binder, although acetone, alcohol, or water, and alcohol mixtures are sometimes employed.

The maximum size of granules used depends on the size of the tablets. A large granule is more quickly and easily made. It is therefore preferable to use as large a granule as will fill nicely into the die of the machine. Ordinary pharmaceutical size tablets are usually made from a granulation that will pass through 12, 16 or 20 mesh sieve, depending on the size of the tablet to be made. It is usually entirely unnecessary to sift out the under size granules and "fines" as the large granules will insure proper flow. Moreover a large uniform granule does not make as smooth a tablet as a granulation containing some smaller granules and "fines".

Binders—Some materials, when granulated with water alone, fall to a powder when the water is removed. In such cases, a small amount of binder is required to hold the material in the granular form necessary for compression. These binders are added most frequently to the granulating agent and they

FIG. 693



Colton's granulation mixer and moistener

serve two purposes; they assist in making the granulation and they give the tablet the desired firmness. The usual binders are sugar syrup, starch paste, glucose, gelatin solution, and acacia or tragacanth mucilage, the choice depending on the use to which the tablet is to be put. Some of these binders may be added in a dry form to the other powdered materials before the addition of the granulating fluid, usually, however, they are added in solution. As a general rule, a binder in solution is twice as effective as one that is dry. Powdered sucrose dissolved in one or two parts of water is one of the most widely used binders in pharmaceutical work. This form of granulation should not be absolutely dry, for then the sucrose will crystallize and some of the binding property be lost. Glucose is an excellent binder and is somewhat stronger than sucrose. Care should be taken not to use it in too great an amount in medicinal tablets, as such tablets have been known to pass through the body without dissolving. Tablets containing glucose are also somewhat hygroscopic and do not keep well in humid weather or in warm countries. Starch paste and gelatin solution are both good binders and make hard tablets. The gums are very strong binders and usually require the use of a disintegrator.

Disintegrators—Most tablets must dissolve or break up in the mouth or stomach. This is accomplished by the use of a disintegrating agent. The

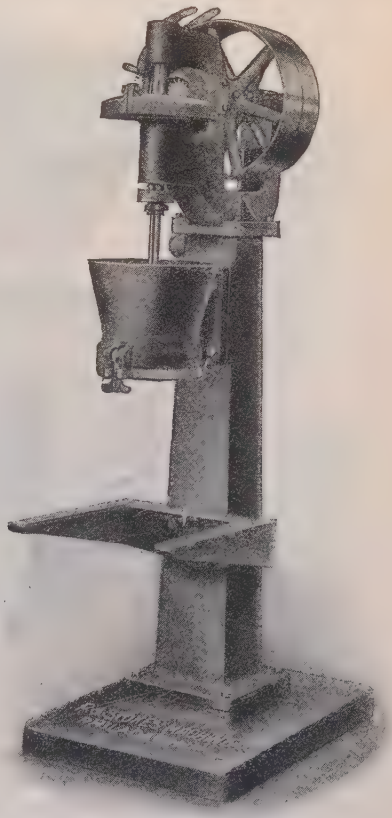
usual agent is powdered corn starch, which has a great affinity for water and swells when moistened, bursting the tablet apart. For rapid disintegration dry starch is added both to the original mixture and to the dry granules. Starch added to the original mixture before wetting it breaks up the separate granules, while three to five per cent of starch added to the finished granulation will separate the granules. Starch introduced as paste has very little if any disintegrating effect.

Drying and Grinding—After the various constituents of the formula have been thoroughly mixed and dampened with the granulating solution, the mixture is spread on shallow trays and placed in a drying closet through which warm air is circulated, or in a few special cases in a vacuum dryer. When sufficiently dry the material is ground to the desired size in a drug mill such as is illustrated in Fig. 694. Figs. 695 and 696 show types of granulating machines in use. Either device may be used to break up or shred the damp granulation to permit more rapid drying. The oscillating granulator is also used to break up lumps formed during the drying process. The oscillator produces less "fines" than the drug mill and should be used when making small monogramed tablets or hygroscopic mixtures. The old hand method of rubbing the damp granulation through a screen with a block of hard wood is seldom used except in cases when a mixture is difficult to manipulate in the

FIG. 694

Hance mill

FIG. 695

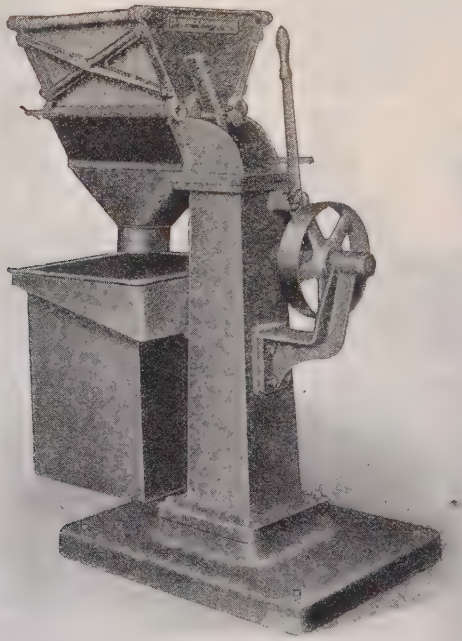


Stokes' granulator

oscillating granulator, or when the quantity to be made up into tablets is quite small.

Lubricants—In practice it has been found necessary to use some substance as a lubricant when the tablets are compressed, otherwise they are apt to stick to the punches or die and cause much annoyance. Finely powdered stearic acid is one of the most efficient of lubricants and may be used in practically all medicinal tablets where it is not objectionable on account of its insolubility or color. One-half of one per cent is usually sufficient to lubricate a well made granulation; seldom more than one per cent. Stearic acid gives excellent results when used to lubricate sugar granulations, or in tablets that are to dissolve slowly. Purified talc has also been extensively used for lubri-

FIG. 696



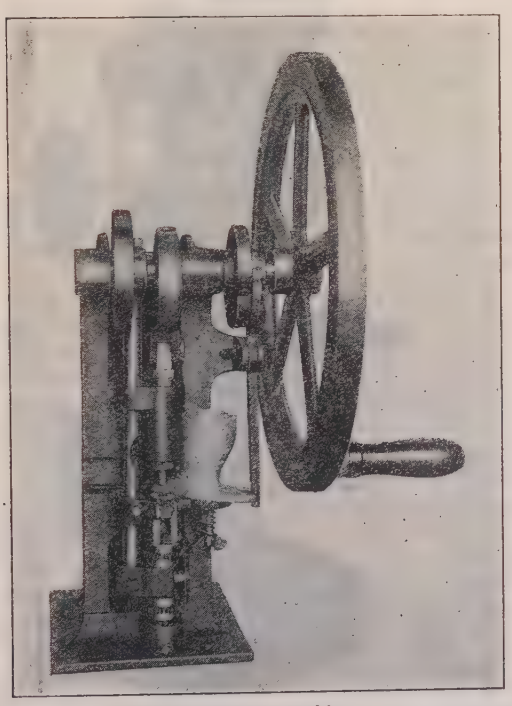
Colton's granulator

cating. From two to five per cent thoroughly mixed with the granules just before compressing is usually sufficient. Talc is not suitable for tablets which are to be dissolved to form a clear solution, nor is its use permitted under the Food and Drugs Act for confections, like mint tablets, or for foods. Boric acid is usually used for soluble tablets, from two to five per cent being required. Liquid petrolatum is largely employed as a lubricant for colored tablets. One or two per cent is added to the otherwise finished granulation and thoroughly mixed. Cacao butter (cocoa butter) and powdered soap have also been used as lubricants. In some cases when the sticking is only on the edges of the tablets and not on the faces, lubrication can be very nicely accomplished by placing a felt washer, soaked in liquid petrolatum, around the lower punch just below the die. Only an exceedingly minute quantity of oil is transmitted to the tablet.

Effervescent Mixtures—These can be handled in two ways. The acid and carbonate mixtures can be granulated separately. The dry granulations

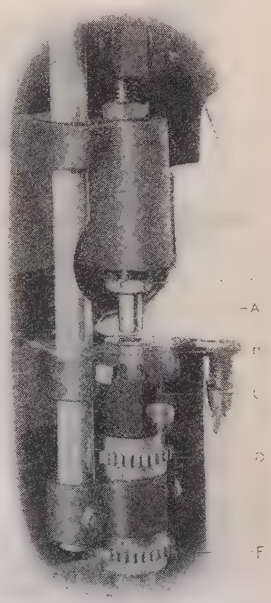
are then mixed and lubricated with three or four per cent of boric acid before compressing. Another method is to heat the whole mixture in a steam-jacketed pan until the water of crystallization in the citric acid causes the mass to fuse. The material should be stirred constantly during the heating process so that it will heat uniformly. As soon as all the fine particles adhere, the material is immediately screened and dried at a low temperature in an air dryer or in a vacuum dryer. The dry granules are lubricated with boric acid before compressing. If the mixture contains a high percentage of citric acid, it may be necessary to partly dry the acid before mixing, so that there will not be too much water set free in the fusing process. These granulations must be

Fig. 697



Eureka tablet machine

Fig. 698



Enlarged view of punches and die

lubricated before compression, using a soluble substance, since they are to produce a clear solution.

Compressing Machines—A variety of automatic machines are now in use for making compressed tablets. The simplest modern machine suitable for the pharmacist is the Eureka tablet machine made by the F. J. Stokes Machine Company, of Philadelphia. This machine, shown in Fig. 697, is entirely automatic and will make 100 accurate tablets per minute of the ordinary pharmaceutical sizes. Adjustments for weight and pressure are very easily made. The enlarged view, Fig. 698, shows the principle on which this machine and practically all single punch machines operate. "*A*" is the upper punch or compressor just leaving the die "*B*". The tablet is shown in the die after it has been compressed. This will be raised by the lower punch "*C*", to the surface, where the feed cup will eject it and fill the die with another

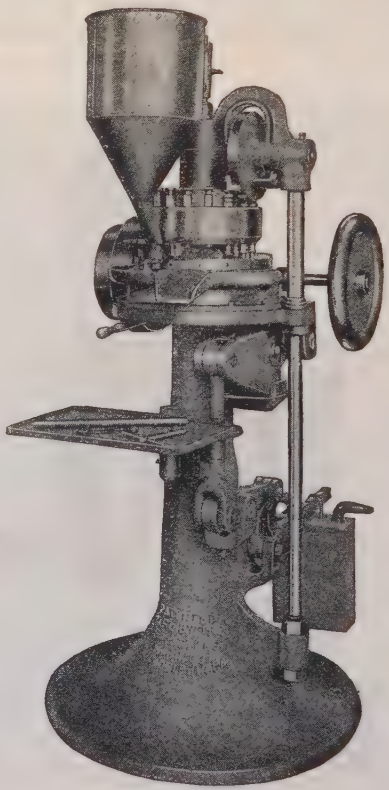
charge of material, upon which the operation will be repeated. "*D*" is the adjustment for regulating the lower punch so that it ejects the tablet properly. "*E*" is the adjustment for regulating the weight of the tablet, and "*F*" is the adjustment for controlling the pressure or density of the tablet.

Fig. 699 illustrates a power driven single punch machine that operates on the same principle as the Stokes' Eureka Machine described above. The F. J. Stokes' Machine Company of Philadelphia, and the A. H. Colton Company of Detroit build machines of this type and adjustments for weight and pressure are similar on both. A single punch machine will produce from 25,000 to

Fig. 699

Single punch tablet machine

Fig. 700



Stokes' rotary tablet machine

40,000 tablets per day. These machines are well suited to the smaller manufacturing pharmacist who handles a varied line of tablets. The machines can be quickly cleaned and easily changed to manufacture different sizes of tablets.

Compressing machines of the rotary type, illustrated in Fig. 700 are used when the required production is larger. By reducing the cost of manufacture they have revolutionized the tablet industry. A rotary machine will make from 200,000 to 500,000 tablets per day. Its method of operation is exceedingly simple. A head carrying a number of sets of punches and dies revolves continuously while the granular powder runs from the hopper, through a feed frame and into the dies. Compression takes place as the upper and lower punches pass between a pair of rolls. The tablet is then ejected. Operation is almost noiseless and without waste, and the smooth motion of the punches reduces to a minimum the tendency of the tablets to cap. Adjustments for

weight and pressure can be made without the use of tools while the machine is in operation. On the Stokes' Rotary Machine illustrated, a safety weight cushions each compression and relieves the machine of all shock and undue strain. The punches and dies can be readily removed for inspection and cleaning. By inserting different sets of punches and dies the same machine can be used for producing a great variety of sizes and shapes.

Punches and dies used in tablet compressing machines require attention and care for best results. They must be highly polished and kept free from rust and imperfections. When not in use they should be removed from the machine, thoroughly cleaned and then coated with petrolatum.

Adjusting the Punches and Dies of a Single Punch Machine—The correct adjustment of the punches and dies in the machine is an important part of the knowledge required for tablet manufacture. On the single punch type of machine the lower punch is first fastened in the socket, then the die put into place in the bed of the machine, and the set screw, holding it in position, tightly fastened. The upper punch is now slipped into place, the machine turned over so that the punch enters the die, and then it is fastened. If the upper punch is tightened in its socket, when not entered in the die, it may strike the side when the machine is turned over and injure both punch and die. Having fastened the die and punches, the lower punch is now adjusted so that when it rises to the highest point it will be exactly flush with the top of the die. If it rises above the face of the die, the shoe which throws off the tablets and afterwards feeds in the granulation, would strike it and injure the punch, and probably jam the machine. On the other hand, if the punch, when it rises to the highest point for the ejection of the tablet, remains below the face of the die, the mechanism which throws off the tablet will cut the tablet in half. The lower punch must next be adjusted so that the cup-like opening in the die, produced by the punch dropping to the lowest point, will hold exactly the weight of granulation required for each tablet. This is determined by weighing out the amount of granulation for one tablet, say three grains, dropping the punch to the lowest point and pouring in the granulation. It should exactly fill the opening and remain flush with the top of the die, corresponding to the condition when the granulation is deposited by the feeding mechanism passing over the die. If the granulation will not all enter the opening, the punch must be lowered, and, if the opening is not completely filled, the punch must be correspondingly raised. The next step is to regulate the pressure; this is determined by the position of the upper punch. The opening in the die is filled with the required weight of granulation and the machine is slowly turned over, by hand, until the upper punch compresses the tablet. If the punch is too low, the machine jams and the fly-wheel cannot be turned, while if too high the tablet will be soft. Its position is therefore adjusted until the tablet possesses that consistence which is recognized as giving the necessary firmness without extreme hardness. A tablet of proper consistence may be readily broken in half between the thumb and fingers, but will not break when dropped upon the floor. The feeding device is now put into place and the granulation poured into the hopper, and the machine started. The weight of the tablets should be carefully checked from time to time by taking the weight of a multiple of tablets, say ten or more.

As the tablet is thrown from the machine it is always accompanied with more or less powder or uncompressed granulation. Various plans have been proposed to free the tablets from this powder, the most common being the sifting of the tablets. A blast of air from a hand bellows or from a compressed air reservoir, applied to the surface of the tablets during the sifting process is

also helpful. Sometimes the tablet, as it leaves the machine, is made to slide down an inclined trough which is made partially of coarse sieve cloth; the powder is thus collected before the tablet reaches the container.

The adjustment of the punches on a rotary tablet machine is not readily described and those who are required to operate this type of machine must acquire the mechanical knowledge through actual experience with the machine. Nevertheless many of the principles just described also apply to the adjustment of punches on the rotary machine.

The following are typical formulas, illustrating many of the foregoing points. They are arranged as usually found on the formula cards of a manufacturing pharmaceutical firm.

Tablets of Acetanilid, 1 grain	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Acetanilid	1 gr.	1		
	Starch			6 2/3	
Granulate with 20 per cent gelatin solution					
Add					
	Starch			1 1/3	
Finished weight			1	8	

Make 1 1/2 gr. tablet, using 7/32 inch die

Tablets of Acetanilid and Sodium Salicylate Compound	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
✓	Acetanilid	2 1/2 gr.	2	8	
	Sodium Salicylate	1 3/4 gr.	1	12	
	Caffeine	1/4 gr.		4	
Granulate with 10 per cent acacia solution.					
	Sodium Bicarbonate	1 gr.	1		
Granulate with 10 per cent acacia solution					
Mix granulations					
Add					
	Starch			1	
	Talc			5	
	Methyl Salicylate			1 1/2	
Finished weight			6		

Make 6 gr. tablet, using 3/8 inch die

Tablets Acid Arsenous 1/30 grain	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Acid Arsenous	1/30 gr.			233
	Powd. Sugar	1 gr.	1		
	Starch			6	204
Granulate with 10 per cent acacia solution					
Add					
	Talc			1	
	Liquid Petrolatum				90
Finished weight			1	8	

Make 1 1/2 gr. tablet, using 7/32 inch die

Tablets Ammonium Salicylate Compound	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Ammonium Salicylate	2 gr.	2		
	Acetanilid	1 1/2 gr.	1	8	
	Dover's Powder	1/4 gr.			
	Use: Powd. Opium				175
	Use: Powd. Ipecac				175
	Caffeine	1/4 gr.		4	
	Powd. Sugar			8	88
Granulate with gelatin Solution					
	Powd. Camphor	1/2 gr.		8	
	Precip. Calcium Carbonate			4	
Granulate with 1/4 pint syrup					
Mix granulations					
Add					
	Starch			1	292
	Talc			3	150
	Liquid Petrolatum				96
Finished weight			5	8	

Make 5 1/2 gr. tablet, using 3/8 inch die

Tablets Acid Sodium Phosphate, 10 grain	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Sodium Biphosphate or Acid Sodium Phosphate	10 gr.	10		
Granulate with water Add					
	Boric Acid			8	
Finished weight			10	8	

Make 10 1/2 gr. tablet, using 7/16 inch die

Tablets Aspirin, 5 grain*	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Acetylsalicylic Acid or Aspirin	5 gr.	5		
	Powd. Starch			9	146
Granulate with Starch Paste					
Finished weight			6		

Make 6 gr. tablet, using 3/8 inch die

* Aspirin, granulated for compression, is also obtainable commercially

Tablets Atropine Sulphate, 1/100 grain	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Atropine Sulphate	1/100 gr.			70
	Lactose or Milk Sugar		1	5	367
Granulate with 5 per cent acacia solution Add					
	Talc			1	
	Starch			1	
Finished weight			1	8	

Make 1 1/2 gr. tablet, using 7/32 inch die

Tablets Alkaline Antiseptic	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Sodium Bicarbonate	5 gr.	5		
	Sodium Borate	5 gr.	5		
	Sodium Chloride	5 gr.	5		
	Sodium Benzoate	7/24 gr.		4	292
	Sodium Salicylate	7/24 gr.		4	292
	Tartaric Acid	1/4 gr.		4	
Mix and dry in drying closet					
Do not granulate					
Add					
	Boric Acid		1		
	Eucalyptol				204
	Thymol				204
	Menthol				102
	Methyl Salicylate				102
Finished weight			16	12	350

Make 16 4/5 gr. tablet, using 9/16 inch die

Tablets Aloe and Mastic	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Powd. Aloe	2 gr.	2		
	Powd. Mastic	1/2 gr.		8	
	Powd. Rose Leaves	1/2 gr.		8	
	Powd. Starch			2	
Granulate with alcohol					
Add					
	Talc			2	
	Liquid Petrolatum			1/2	
Finished weight			3	4	

Make 3 1/4 gr. tablet, using 5/16 inch die

Tablets Aloin, Belladonna, Strychnine, and Cascara	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Aloin	1/5 gr.		3	88
	Powd. Ext. Belladonna Leaves	1/8 gr.		2	
	Strychnine Sulphate	1/120 gr.			58
	Powd. Ext. Cascara Sagrada	1/2 gr.		8	
	Powd. Sugar			3	88
	Precipitated Calcium Carbonate			6	115
Granulate with diluted alcohol					
Add					
	Starch				175
	Talc				263
	Liquid Petrolatum				88
Finished weight			1	8	

Make 1 1/2 gr. tablet, using 1/4 inch die

Tablets Iron, Quinine, and Strychnine	INGREDIENTS	In each tablet	In 7000 tablets		
			lb.	oz.	gr.
	Reduced Iron	1/2 gr.		8	
	Quinine Sulphate	1/2 gr.		8	
	Strychnine Sulphate	1/120 gr.			58
	Powd. Sugar			4	233
Granulate with water					
Add					
	Talc				292
	Liquid Petrolatum				10
Finished weight			1	4	

Make 1 1/4 gr. tablet, using 7/32 inch die

Lozenges Ammonium Chloride Compound	INGREDIENTS	In each tablet	In 7000 tablets

Finished weight			5		

Make 5 gr. tablet, using 3/8 inch die

CHAPTER CV

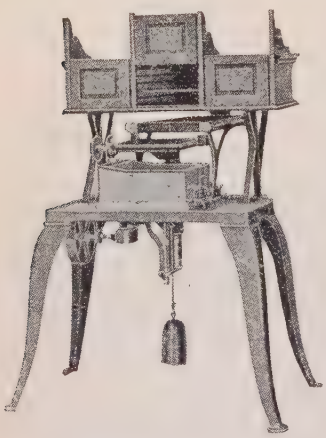
COATING PILLS AND TABLETS

Pills are coated with sugar, chocolate, gelatin, silver leaf, gold leaf, salol, and talcum or French chalk, etc., with the view of masking their taste or rendering them enteric.

Pills cannot be satisfactorily coated with sugar in the small way without much labor. This is not the case with gelatin coating. It is quite possible for the pharmacist to coat pills with gelatin and be able to dispense them in fifteen minutes.

Gelatin Coating—The coating of pills with gelatin is an old process. Formerly each pill was impaled upon a long needle, dipped into a solution of gelatin, and the end of the needle stuck into a cork to permit the coating to dry. This slow process was improved by Charles B. Allaire, who devised a machine for dipping a number of pills at once, and also one for stripping the needle bar. Since then many machines have been introduced for coating pills with gelatin, but all forms have been superseded by the form of coater made by Colton in which the pill is held upon a metal point with the aid of a vacuum.

Fig. 701



Gelatin coating machine

In Remington's "Practice of Pharmacy", 6th edition, some of the older forms of pill coaters are described such as those devised by Patch, Franciscus, Maynard, and Palethorpe.

The holding of the pill upon a metallic point by the aid of a vacuum was devised by J. B. Russell and the Colton machine (Fig. 701) is simply a perfection and adaptation of his patent.

The machine illustrated has the capacity to coat 50,000 pills in ten hours. A vacuum pump and tank is an essential part of the outfit, and it may be located in any convenient place. After the pills are made and seasoned they are ready for coating. The pill drawer is first stored with pills. The front of this drawer contains a feeding plate, registering with the dipping plate. The latter is now placed upon the vacuum jacket and clamped to place; the pill drawer is then pulled forward, which brings the feeder exactly in proximity with the dipping plate. The vacuum being on, the pills are carefully brushed upon the feeding plate, when every receptacle will be filled. The pills are held in place by the force of the suction supplied from the exhaust tank. The pill drawer is returned to its place, and the vacuum jacket (containing the dipping plate and pills) is now reversed for immersion. This done, the jacket is inverted to the first position and the vacuum shut off. The plate is released from its seat and then placed in the kiln to dry the pills, after which the operation is repeated, leaving but one plate (for the beginning of reverse operations). This is placed upon the vacuum jacket, precisely in the same manner as previously described. The plate is now taken from the drying kiln and placed securely upon the transferring apparatus; then, with the lever, the two are brought into close

contact, one above the other. The force of the vacuum acting through the perforations will immediately release the pills, transferring them instantly to the dipping plate on the jacket. The operator then proceeds to immerse the uncoated half of pills in the manner first described.

Pills may be coated with gelatin by cutting the pill cylinder to its center, placing in the cleft a piece of sewing silk, rolling it, dividing it into pills, dipping in gelatin solution, drying, and cutting apart.

Even this improved gelatin coating method is being today largely replaced by the sugar coating method in which gelatin is made a part of the mixture as has already been described. This possesses the advantage of greater speed and marked reduction in machinery and labor cost as compared with the dipping process.

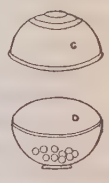
GELATIN COATING SOLUTION (FOR DIPPING)

Gelatin (best grade sheet gelatin)	2½	oz. av
Powdered boric acid	120	gr.
Mucilage of acacia	2	fl. oz.
Distilled water	7	fl. oz.

Macerate the gelatin with the water until it softens, dissolve it by heating on a water bath, and add the boric acid; then slowly add the mucilage of acacia, and strain the mixture. If sweetening is desired, a very small quantity of soluble gluside may be added.

Pearl Coating—This term is applied to the method of coating pills with finely powdered talc or French chalk; the process is similar to that used in silver coating (see below), by placing in a globular box (see Fig. 702) a mixture of very finely powdered talc and sugar, and, having covered the pills with the adhesive mixture, they are rotated until coated. A polish may be given to the surfaces by rotating the pills in a box coated on the inside with paraffin.

FIG. 702



Silver coater

Gold or Silver Coating—The coating of pills with gold and silver leaf dates from the eleventh century A.D., when it was introduced by *Avicenna*. Pills may be coated with gold or silver leaf by first placing a drop of syrup of acacia, or a small quantity of a thick mucilage of acacia, in a mortar, and, after carefully spreading it over the surface with the end of the finger, dropping in the pills, rotating them, with the aid of the finger if necessary, so that they shall be uniformly coated with a very thin layer of mucilage, and then dropping them into the gold or silver leaf contained in the coater. This is merely a smooth, globular box, made of horn or turned wood, opening in the middle (see Fig. 702). A tin ointment box or even a round pill box may be used in applying these coatings. When the pills are rotated, they soon become coated with the leaf, and are then ready to dispense. In the absence of a globular box a large sized pill box may be used. This process is also described in the N. F. V.

Other extemporaneous coatings suggested by the N. F. are as follows:

Extemporaneous Sugar Coating—Quickly roll the pills, freed from dusting powder, on a filter paper saturated with mucilage of acacia, until uniformly but superficially moist, then immediately transfer them to a porcelain dish containing a mixture of eight parts of powdered sucrose or lactose and two parts of powdered acacia, and rapidly rotate them until covered with a firm white coating.

Extemporaneous Chocolate Coating—Quickly roll the pills, freed from dusting powder, on a filter paper saturated with mucilage of acacia, until uniformly but superficially moist, shake them at once with powdered cocoa

until well coated, then immediately transfer them to a clean, warmed porcelain dish, and rapidly rotate them until a smooth coating is produced.

Tolu Coating—Drop the pills, freed from dusting powder, into a porcelain dish in which a thin layer of equal volumes of tincture of tolu and ether has been previously placed, and rotate them until thoroughly coated with the mixture. Turn them at once into another dish of the same kind and size, and rotate for a few moments to remove the excess of mixture, and while the pills are still shining, but not too moist, transfer them to a third dish, previously coated with a very thin film of oil, which has been applied by the tips of the fingers, and rotate them until dry. A second or third coating may be applied in the same manner, if necessary.

Stearic Acid Coating—The use of stearic acid as an enteric coating for pills has been suggested by William G. Toplis. The coating is applied by adding a saturated, ethereal solution of stearic acid to the pills, in a dish, and at the same time rotating the pills. The solution is added carefully, only a few drops at a time, until the coating is complete.

THE SUGAR COATING OF TABLETS AND PILLS

The following description of the process for coating pills and tablets with sugar and also with gelatin has been prepared by F. J. Stokes and is copied here with permission.

The process of coating tablets and pills has been surrounded with more or less secrecy and has in consequence been considered by those unfamiliar with it as quite difficult. It is in reality quite simple and can be mastered by anyone who uses ordinary judgment and common sense. The following instructions should be ample after a little experimenting, to enable anyone to undertake the work with assurance of success. There are several fundamentals to bear in mind which are set forth in the paragraph headed *General Precautions.*

Tablets were formerly coated by what is called the hot process, that is to say, they were placed in a revolving coating pan which had copper steam coils wound around the outside of the pan. This heated the pan and accelerated the drying of the syrup as it was applied to the tablets. A considerable portion of the syrup dried in a hard layer on the surface of the pan and was difficult to recover or was lost. It was later discovered, that by blowing air upon the pills or tablets, the drying took place about as rapidly, and little syrup was deposited on the surface of the pan. As a result the cold process, as it is termed, is now very generally used. In some cases warm air is used, which increases the rapidity of the drying. Warm air is not necessary, however, and many manufacturers use cold air rather than incur the expense of a heating box for heating the air. Steam-heated pans are preferred by some for sugar coating those compounds which contain bromides and other drugs which rapidly absorb moisture.

Equipment—The equipment of a coating department includes one or more coating pans, polishing pans, a fan blower, a syrup kettle or cooker, glass graduates, stirring rods, scales, dippers, workbench, drying closet, screens and containers for the stock solutions and powders.

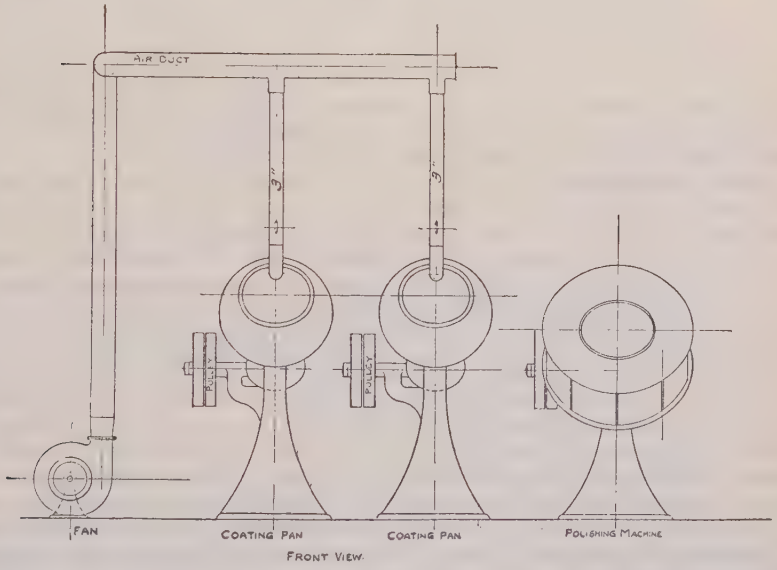
Coating Pans—These can be of copper or galvanized iron, the former being preferred on account of their shape (see Fig. 703). The galvanized iron pans have corners where the sections are fastened together, in which the tablets are apt to stick, and their rolling action is not quite as satisfactory as in the copper pans. The size of the pan depends on the quantity of tablets to be coated at an operation. Usually a number of pans are used so that different lots of tablets

may be coated simultaneously in various colors. The most popular sizes of coating pans are those having a diameter of 24, 30, or 36 inches. The capacity of the pan depends upon the size of the pills or tablets and the thickness of the coating desired. When the uncoated pills or tablets are first placed in the pan, they may seem small in comparison with its size, but when the coating has been finished, the volume of the tablets will be greatly increased. This should not be overlooked when starting to coat. In the table below is given the maximum capacity in one, three, and five grain tablets.

Pan	One grain	Three grain	Five grain
24 inch diameter	100,000	70,000	50,000
30 inch diameter	150,000	125,000	100,000
36 inch diameter	250,000	200,000	150,000

Polishing Machines—A cedar wash tub, about 3 feet in diameter and 16 inches deep, may advantageously replace the ordinary copper pan for

FIG. 703



Coating and polishing plant

polishing the coated pills or tablets. The roughly coated pills or tablets are placed in the tub and while rolling the polishing wax solution is added until the tablets are wet (about ½ fl. oz. of solution to 30,000 tablets). They are kept rolling until polished. The advantage of the wooden tub over the copper pan is that the tablets rolling in the metal tub become warm, thus melting the wax and making them hard to polish. With the wooden tub this does not happen. If a coating pan is used, it is generally lined with canvas. The canvas is cut so as to fit the pan and glued to it. As a coating pan is more expensive than a polishing machine, and as the labor involved in adapting the former for polishing is considerable, it is obvious that it is more economical to have a separate polishing machine or machines. One polisher is required for polishing white coatings, and can be used for no other color, as chocolate and colored coatings stain the canvas lining, and the color would come off and discolor sub-

sequent white lots. For the same reason one polisher is kept exclusively for chocolate coating and a third for polishing the various pink, blue, green, or yellow colors. As the polishing process requires only a relatively short time, as compared to the actual coating process, three polishing machines will handle the output from many coating pans. An inexpensive arrangement which is satisfactory for small production, is to insert into the mouth of a coating pan a cylindrical wooden tub, so shaped that it wedges in the opening of the pan. Several of these can be had at small expense, and a coating pan can be immediately converted into a polisher by inserting one into the pan. The polishing pans illustrated in Fig. 703 are also largely used.

Fan Blowers—The standard type of fan blower of sufficient size to supply an air blast to the pans is required; a 15-inch blower for one pan and an 18-inch blower for three or four pans. This fan can be placed on the floor, or hung from the ceiling. A pipe line is extended along the ceiling over the pans, and from this smaller pipes are extended down to the mouth of each pan. These drop pipes should be fitted with a damper so the air blast can be controlled, and they should end with a loose spout which can be removed when emptying the pan. The illustration in Fig. 703 shows this arrangement of the pipes in relation to the pan. The standard gutter spouting with elbows and fittings as supplied by tinsmiths can be used. As stated above, some coaters prefer to blow warm air to hasten the drying, especially in humid weather. For heating air a steam coil or gas heater is placed in a closet and the suction inlet of the blower connected with the closet; this will meet all requirements.

Cooking Apparatus—The stock gelatin solution and the syrup solution used for sugar coating tablets require heat in their preparation and application. A small steam-jacketed, copper kettle of three to five gallons capacity is very satisfactory for this purpose. A gas stove on the workbench with suitable agate double-boilers will answer, however. The steam-jacketed kettles or gas heaters should be conveniently situated, so that the operator, when dipping out solutions will not have to carry them far to the coating pans. The work bench should face the pans, and a suitable aisle should be arranged between it and the pans. A drying closet will be found of great convenience for drying the tablets before they are placed in the coating pan, and also for drying combinations which absorb moisture. A mortar and pestle are convenient for preparing colored solutions, and should be a part of the equipment, also pint and quart measures and glass stirring rods. The equipment is completed with a set of perforated sieves for separating the different sizes of tablets which may be coated in the same pan, at the same time. They are also useful for screening out broken tablets.

Preparation of Stock Solutions and Sub-Coating Powders—Before the operator can start the coating, the gelatin solution must be prepared for the under or sub-coating, and also the starch and sugar mixture, which is dusted on when forming the under or sub-coating. The syrup solution and stock colors for coloring the syrup must also be prepared. The following formulas for these solutions and powders give very satisfactory results. They are subject, however, to considerable variation, to suit the ideas of the operator after he has become experienced. There are rarely two coaters who use exactly the same formulas.

Gelatin Solution for Sub-Coating—This is prepared by dissolving 2 pounds avoirdupois of powdered or granulated gelatin and 24 pounds avoirdupois of granulated sugar in 2 gallons of warm water, mixing thoroughly and bringing to a slow boil. When thoroughly dissolved, strain, and put in a can or crock. Some coaters add to the above mixture 24 ounces avoirdupois of powdered

acacia. This is not necessary, however, and the solution is stickier and harder to handle than without the acacia. This solution will gelatinize when cold, but will always liquefy when heated, and should always be applied hot.

The following solution is recommended by L. T. Andrews who has had large experience in pill coating:

Gelatin	1 lb. av.
Acacia	1 lb. av.
Water	2 gallons

Allow the mixture to stand until the gelatin has softened, then dissolve by the aid of heat and add 25 pounds of granulated sugar to the hot solution. Again warm and stir until the sugar dissolves and strain through cheesecloth. This formula makes about 4 gallons, and as it sets to a stiff jelly it may be kept for some months. When needed, it must be liquefied on a water bath and used warm.

White Dusting Powder—This as used in connection with the gelatin solution for sub-coating is a mixture of 36 pounds of powdered sugar and 12 pounds of powdered starch, mixed thoroughly and screened through a No. 36 sieve. Some coaters prefer to add 2 pounds of powdered talc and 2 pounds of powdered acacia to the above. The talc assists materially in producing a smooth sub-coating.

Chocolate Dusting Powder—This, as used for sub-coating chocolate-coated tablets, is the same as white dusting powder with the addition of 6 pounds of powdered cocoa or powdered chocolate. This dusting powder is screened in the same manner as the white. The dusting powders, or "stock powders", as they are called, can be stored in galvanized or other suitable containers.

Mr. Andrews uses the following powders:

White Dusting Powder—	Precipitated Chalk	4 lbs.
	Pure White talc	1 lb.
	Starch	1 lb.

Mix, and pass through a No. 80 sieve.

Brown Dusting Powder—	Umber	1 oz. av.
	Powdered talc	3 lb. av.

Mix, and sift through a No. 80 sieve.

Starch Powder—	Corn starch	5 lb.
	Powdered talc	½ lb.

Mix, and pass through a No. 80 sieve.

Syrup used for coating after the sub-coating has been applied is composed of 30 pounds of granulated sugar dissolved in 3 gallons of water and brought approximately to the boiling point. The syrup is then strained through cheesecloth and when cool is ready to use. This syrup is used in this form for coating white coated tablets. It is applied cold in all cases.

Mr. Andrews uses the following syrup which is of special value in rounding the pills:

Granulated sugar	4 lbs.
Water	1½ pts.

Dissolve the sugar with the aid of heat and add the following which has been made into a paste:

Corn starch	3 oz. av.
Powdered talc	1 oz. av.
Water	8 fl. oz.

Mix thoroughly. Heat to boiling, strain through cheesecloth, and add sufficient water to make ½ gallon.

Coloring Solutions for Syrup—If the coating is to be colored, the syrup is tinted by adding to it coal-tar color prepared in the following manner: One ounce of color dissolved in one pint of hot water. The dye used must be one of the "Certified Food Colors", see page 841. These solutions which are afterward referred to as stock solutions, are usually prepared and kept ready for use.

Wax solution—The solution used for polishing is made by dissolving one ounce of carnauba wax in one pint of acetone. Beeswax may be used or preferably a mixture of 1 part of carnauba wax to 3 parts of beeswax.

Mr. Andrews suggests the following polishing wax:

White beeswax	1 lb. av.
Carnauba wax	2 oz. av.

Melt together, strain, and cool.

Polishing wax solution:

Dissolve 600 grains of the above polishing wax in 1 pint of high grade gasoline with the aid of heat. The solution must be used while warm as it precipitates on cooling.

Tablets—These should be compressed with high convex faces and with as thin an edge as possible, and at the same time conform to good proportions. Tablet punches are usually made with three degrees of concaved faces, called standard, deep, and extra-deep concave. The deep concave is preferable for most purposes, as it forms a satisfactory shape for either coated or uncoated tablets. The thinner the edge of the tablet the easier it is to cover it and the corners with the coating. The tablets should be screened to remove all dust and broken tablets before placing in the coating pans.

General Description of the Process—Before taking up in detail the various steps in coating tablets the process will be briefly explained. The tablets, after cleaning and removing defective ones, are placed in the coating pan and subjected to three to five coats, depending on the tablets. Each sub-coat consists first of the wetting of the tablets with the gelatin solution and, when partially dry, sprinkling with the dusting powder. By this means the tablets are rapidly filled out and rounded. Following the sub-coating the tablets are given a sufficient number of applications of the syrup to produce a hard, smooth finish, the last two or three syrup coats, which are known as the finishing coats, receiving special attention. The tablets are then polished with the wax solution.

It is easier to coat tablets white than any other color. Only a few syrup coats are required if the sub-coating has been properly done. Chocolate coating can be quickly done, as it also requires only a few syrup coats. Chocolate coating, however, may give the beginner some trouble to keep the colors uniform. This may occur if the finishing coats are allowed to dry too quickly. Colored coatings other than chocolate require a longer time to coat, due to the fact that the tint has to be developed slowly.

After becoming familiar with the technic of coating it will be found economical to coat two or possibly three sizes of tablets in the same pan at one operation. It is apparent that this can only be done when the tablets have sufficient difference in size to permit of their complete separation by screening after they are coated. When this practice is followed it is advisable to sub-coat the different batches separately, and then syrup-coat them together in the one pan. There are two reasons for sub-coating separately. One is to prevent the transfer of odor or powder from one formula to the other. The other is

that where large and small size tablets are sub-coated together the small tablets are apt to stick to the larger tablets. This tendency is greater in the sub-coating, due to the heavier gelatin solution which is used, than with the syrup coating.

The formulas given above and the detailed instruction which follows are the best practice so far obtained. They no doubt can be modified to advantage in special cases, as well as improved, and the intelligent coater should always endeavor to simplify the work wherever possible, if a satisfactory coating results.

As an illustration and to explain the processes more clearly, it is assumed that 70,000 three grain cascara sagrada tablets are being chocolate coated. Use a coating pan of 24 inch diameter, if available, as it will be easier to start with a pan which is in proportion to the size of the batch. A coating pan of 30 inch diameter, of course, may be used. It is difficult, however, to coat a very small quantity of tablets in a large pan, as they will have an increased tendency to stick to the pan after each application of gelatin solution and syrup, and require more stirring to overcome this and to prevent their sliding before they commence to roll properly.

While the beginner will of necessity have to start with a clean pan, it will be found later on that the sub-coating can be accomplished more readily by placing the tablets in a pan which is slightly encrusted with syrup from a previous coating. The reason is that the tablets, when moistened with the gelatin solution in a clean pan, will slide as one mass rather than roll, and will require much more stirring by hand to break up the mass and start them rolling than if the pan were already coated with syrup.

Sub-Coating—When the tablets are placed in the pan, the gelatin solution for sub-coating should be warm and conveniently located. Dip out one pint in an agate measure and have a scoop full of chocolate powder at hand. As the tablets revolve, pour the gelatin solution over the tablets, stirring them with the hand to distribute the solution. Keep stirring to make the tablets roll if possible, and when the gelatin has partially dried and is tacky, sprinkle on the chocolate dusting powder until there are no wet tablets showing. The chocolate powder can be sprinkled on by hand, and wet areas in the tablets can be sprinkled as they appear. The tablets will begin to roll freely as soon as the powder is dusted on. Avoid using an excess quantity of powder, as this will roll in the pan and affect the smoothness of the succeeding coat. Should excess powder accumulate it will appear at the back of the pan, and the powder and tablets at the back can be scooped out and separated, the tablets being put back in the pan. After the chocolate powder has been applied and taken up by the tablets, and not before, turn on the air blast until the coating is perfectly dry. This requires about fifteen minutes. The operator can test for dryness by scraping with the finger-nail or with a knife to see if it will powder off. Sometimes the tablets split or cap during the first sub-coating, and there are always a few tablets which stick together. It is advisable to rescreen tablets to insure the removal of such before applying the second sub-coating. Three or possibly four coats are applied to complete the sub-, or under-coating. This sub-coating is very important, as upon it largely depends the smoothness of the finished tablets.

Syrup Coating—After the tablets have been sub-coated, the chocolate syrup is applied. It is advisable to again screen the tablets to remove the broken ones, and if the pan is too rough from encrustation of sub-coating, it should be washed. The color of the chocolate sub-coating will be much lighter than the color of the finished tablets. Fewer coats of the chocolate syrup will be

required if the tablets are first given two light coats of chocolate syrup, having a double quantity of chocolate brown paste to intensify the color. Mix a pint of this intensified coloring syrup and apply it in two doses. It is difficult to state the exact amount of syrup a given quantity of tablets will take up; about one pint would be the proper quantity for each application of syrup to the quantity of tablets under consideration. The quantity of syrup, however, should be as much as the tablets will take up and not form into a mass so they do not roll. Pour this over the tablets as they revolve, distributing it as much as possible while pouring, and at the same time stirring with the hand until the syrup is evenly mixed and the tablets are rolling freely. Do not turn on the air blast until the tablets roll freely, and then blow air until dry, requiring approximately twenty minutes. There should be a distinct improvement in the smoothness of the coating after the first application of the chocolate syrup is added, and this improvement will become more pronounced as the applications are continued. After two coats of the darkened syrup, the operator can proceed with the standard chocolate syrup, applying as many coats as are needed to properly round the tablets, so the edges and corners are smooth and show a uniform color. From five to ten coats may be required to produce the necessary finish. If pin holes appear in the coating they can be filled in by allowing the syrup to dry more slowly, the theory being, the longer the coating remains in a plastic condition the more working it will receive by the rolling action of the tablets. The operator can tell from time to time how the tablets are smoothing up by breathing on several held in the hand close to the mouth. This test reproduces the color and luster which will be obtained after they are polished with the wax solution. If the tablets do not show up smooth and polished when so tested, probably no amount of polishing will materially improve their appearance. This practice of breathing on the tablets is unquestionably to be condemned from a hygienic standpoint, but there seems no other way for the beginner to get a quick line on the results. It is imperative that these few test tablets be discarded.

Finishing Coating—The tablets are now ready for finishing. If the pan is rough it should be washed out and dried. Give the tablets a light application—say, 3 or 4 ounces—of chocolate syrup, with the color, however, cut down two-thirds in quantity. The chocolate paste does not enter into solution with the syrup, as is the case with the aniline colors, and by reducing the amount of the chocolate brown paste in the three finishing coats, a harder surface is produced which takes a better polish. These finishing coats should be allowed to dry without the air blast. On the third or last coat, just before the tablets are dry, stop the pan and cover the opening with a cloth. By doing this the tablets will dry more slowly and retain a better and more uniform color than if they were revolved. It will be well to turn the coating pan a half revolution by hand from time to time to expose a fresh surface of the tablets. If this is not done, those tablets which are on top will dry a lighter color than those below. It will take about two hours to dry the tablets in a stationary basin. The operator may be able to use an air blast for the final drying, but the pan must be stationary, except when revolved by hand in order to expose a fresh surface or it is liable to produce uneven colors.

Polishing—The tablets should now be ready for polishing and are transferred to a polishing pan. While revolving in the polisher, pour two ounces of wax solution over the tablets. A wide-mouth bottle with a shaker top makes a suitable container for the wax solution. Two or three shakes of the solution should be sufficient. Stir the tablets with the hand in order to distribute the solution thoroughly through the tablets. Allow the tablets to revolve until

the solvent has evaporated and then dust on from a shaker a small amount of talcum powder. The talcum is usually applied with the ordinary commercial shaker talcum box, and only two or three shakes are necessary. The luster, or polish, should appear immediately. It may be improved by a second or possibly a third application of wax solution and talcum. Leave the tablets in the polisher for fifteen or twenty minutes, or longer if desired. When removed from the polisher the tablets should be spread on trays and dried before placing in the containers.

White Coating—Tablets are white coated in the same way as they are chocolate coated with the exception that white dusting powder is used in place of the chocolate dusting powder when sub-coating. Plain syrup is used for the coating and finishing. Some coaters, in order to get quick results by reducing the number of applications of syrup, load their syrup by mixing with it an additional quantity of powdered sugar. This sugar does not enter into solution and the mixture is made just as heavy as it is possible to pour and distribute over the tablets. By controlling the air blast this coating can be made smooth, and the finishing coats may be applied, using the standard syrup.

Colored Coatings—When tablets are to be coated blue, green, yellow, or red, the same general method applies as described. The sub-coating is applied with white dusting powder, and syrup for the coating and finishing is tinted with the properly colored solution, the tint being intensified as the coating progresses. In other words, the first two or three coats are made by applying syrup of a light tint, the next three coats with syrup of a darker tint, and so on to the end. If the operator attempted to apply syrup tinted to the finished color from the beginning, the result would be a blotchy color, probably due to the fact that the sub-coating, being absorbent, would take up the color unevenly. As an example: take 100,000 tablets of strychnine, each weighing 1 grain and coat them red. Use a 24 inch pan, and, after the tablets have been sub-coated white, apply a syrup which has been colored in the proportion of 1 ounce of stock red coloring solution to one gallon of syrup. Give the tablets two or three coats and then intensify the tint of the syrup by adding more red in the proportion of 2 ounces of stock color to the gallon of syrup. After several coats the color is again intensified by again doubling the proportion of color in the syrup. Always retain some sample tablets of the proper color to be used in matching a new lot. With a little experience the operator can intensify the color of the syrup by judging its color with the eye and without resorting to measuring the exact proportion. When the desired shade and finish have been obtained the air blast should be taken off and the tablets given three or four applications of colored syrup in the manner described for chocolate coating. The pan should be stopped just before the final coat is dry, as explained above. The method for coating tablets in other colors is identical.

When pills are coated with a syrup containing umber and no chocolate, they must not be called "chocolate-covered" or "chocolate-coated". They should be designated "sugar-coated brown".

Special Treatment for Coating Tablets which Absorb Moisture—Some tablets, owing to their contents, require great care in coating to prevent the water in the gelatin solution from penetrating the tablet rather than evaporating. Such a result would prove disastrous, as this moisture, no matter how well the finished coating appeared on the outside, would eventually work out through the coating, discoloring it and producing unsatisfactory results. It is therefore very important that when coating sodium salicylate, and combinations containing iodides, bromides, and other compounds having an affinity for water that care should be exercised to prevent the water "drying

in". There are several methods in use. A small amount of oil applied to the outside of the tablets before applying the gelatin solution is one method. Too much oil must not be used or it will discolor the coating. If a dough is made by adding sufficient starch to a tablespoonful of raw linseed oil and the dough kneaded into a ball, and the ball allowed to roll with the tablets, they will absorb the oil from the dough. The ball will shortly break down and the powdered starch, after the oil has been absorbed by the tablets, will appear in the back of the pan. After this preparation the tablets can be sub-coated in the regular way. Another method is to apply the stock gelatin solution, but in place of the stock dusting powder to apply powdered calcined magnesia. It is advisable to apply an excess of this to be sure of absorbing the moisture in the gelatin solution. Another method, similar to the above, is to substitute powdered acacia as a dusting powder after the gelatin solution has been applied. When the three or four sub-coatings have been applied, the tablets should be dropped in trays of hot powdered starch and dried for a few hours. The application of the coating can then proceed as usual. It is important to have the tablets dry at the start and also to dry them thoroughly after sub-coating to eliminate any moisture which may have dried in.

Re-Coating Tablets—While it is not anticipated that the operator will have bad luck, this may occur occasionally and it will be necessary to re-coat the tablets to prevent loss. If this becomes necessary place the tablets in a dish pan, cover them with water, and stir them with the hand until the edges of the tablets begin to appear. Then pour off the water and cover the tablets with denatured alcohol to absorb the water. Drain off the alcohol, shake the tablets well in a sieve to remove the alcohol, and then put them in a coating pan and revolve under the air blast. When dry they can be re-coated. It may be that the tablets will wash off irregularly and some will be larger than others. If this is noticeable, remove the larger tablets by screening and rewash them in water to reduce their size, or place the smaller ones in the coating pan and give them an extra coat to bring up to the size of the larger tablets.

Time Required for Coating—This depends upon the skill of the operator and as experience in applying the sub-coating increases, few syrup coats are required. It is also evident that if the operator is able to load the syrup with free powdered sugar, the coatings will build up more rapidly and fewer will be required. Some coaters turn out a batch of the ordinary run of tablets in five hours, while others require a day or possibly more. Speed in coating, however, is not the chief end to be gained; it is more important that the coatings be permanent, that they will not break off, and will not discolor due to moisture in the tablets working out through the coating.

General Precautions—Each coat must be perfectly dry before putting on the next application, whether sub-coating or syrup, otherwise the moisture will dry in and will result in a cracked or discolored coating. Always screen the tablets after the first two applications of sub-coating to remove broken tablets. If these are not removed they will stick to the tablets and produce an unsatisfactory result. When the coating pan gets rough inside from too much syrup drying on it, wash it out and the tablets will coat much better. When making white coating, keep away from chocolate coating, as the dust will fly from one pan to another and the white coating will be specked. Be sure the hands are clean and not stained with chocolate or other colors.

Sugarless Coating—This is recommended for tablets or pills to be shipped to tropical climates, and is made by applying gelatin solution instead of syrup. The process is quite similar to that of sub-coating, in that a dry powder of chalk or starch is added to the tablets after they have received an application

of gelatin solution. The dusting powder should contain some powdered tragacanth. The coating is finished with several applications of the gelatin solution alone. This coating cannot be polished with wax, but after the tablets have been allowed to roll in the pan for a few hours a very high luster can be obtained by giving the tablets a coat of very thin solution of tolu, denatured alcohol being used as a thinner.

Method for Preparing Homeopathic Globules or Granules—Place five pounds of XXXX sugar in a 24 inch copper coating pan, having steam coils about the outside for heating. A hot-air blast, however, could be used successfully in place of the steam coil. To the sugar add slowly a hot syrup of about 35° B. density. This syrup can be approximated by dissolving two pounds of sugar in one pint of boiling water.

The syrup is slowly added to the powdered sugar as it revolves in the pan until the globules start to form. If too much syrup is added large globules will form instead of small ones; the small ones are the more difficult to produce. Alternate applications of powdered sugar and syrup are added as the globules form and dry out. It will be necessary to remove the larger globules by screening, the small globules being put back in the coating pan. Those of the correct size are set aside on a tray for further drying, and those which are too large melted down into syrup.

The operator will have to keep stirring the sugar in order to break it up and to separate the globules as they form. The formation of too large granules can be overcome by adding less syrup or making it slightly lighter in density.

Enteric Pills—A number of substances have been employed for the purpose of coating pills, so as to enable them to pass through the acid juices of the stomach and be dissolved in the alkaline intestinal fluids; such pills are called *enteric pills*. It is proposed to use these coatings for four classes of medicine: 1. Medicines that can by prolonged contact cause irritation to the mucous membrane of the stomach—arsenic, salicylic acid, creosote, chrysarobin, quinine compounds, copaiba, cubebs, ferruginous preparations, and especially ferric chloride, opium, mercurial preparations, mercuric iodide and chloride, phosphorus, and all the tænifuge preparations. 2. Medicines that can injure the digestion by forming insoluble precipitates with pepsin and peptones—tannin, alum, lead acetate, preparations of bismuth, silver nitrate, corrosive sublimate, etc. 3. Medicines that are rendered inactive or decomposed by the gastric juice—alkali, bile, soap, calcium sulphide, iron sulphide, pancreatin, etc. 4. Medicines which should arrive in the intestines as concentrated as possible—kousso, santonin, extract of male fern, and alkali. For the purpose of making enteric pills several substances have been proposed, chiefly salol (phenyl salicylate), keratin, and stearic acid. The employment of keratin has been discredited and its use largely discontinued, and stearic acid has not been thoroughly tested so that salol is chiefly depended upon for the making of enteric pills. (See also Enteric Capsules, page 1683.)

Salol Coating—The N. F. V. directions for salol coating are given on page 1732, and, with a little practice, have been found to be satisfactory at the prescription counter. The most important point is to learn the exact time in the cooling of the salol, at which to add the pills. If it is too hot, the coating does not adhere to the pills, but cools on the side of the dish; and if too hot, when the second or third coating is being applied, it melts off the previous coating. On the other hand, if too cool and already crystallizing, it forms small nodules on the pill and an irregular coating results.

The rotating of the pan or dish containing the melted salol should be started before the pills are added and continued, without interruption, until

the coating is hard, which, if the temperature is right, should require only a few seconds. The N. F. directions are as follows:

Drop the pills, carefully freed from dusting powder, into an enameled or porcelain dish, preferably with a flat bottom and straight sides, containing enough phenyl salicylate [approximately 1 gr. (0.06 Gm.) to every 2 gr. (0.12 Gm.) pill], previously just melted by the heat of a water bath and allowed to cool so that on passing the hand along the bottom of the dish there is scarcely any warmth felt, yet the salt remains completely melted. Start the dish to rotating before adding the pills and continue rotation until the pills are coated and the phenyl salicylate has congealed. Repeat this process twice, each time reducing the amount of phenyl salicylate about one-half. Finally, apply a finishing coat by using only sufficient phenyl salicylate to barely coat the dish when melted, repeating the operation as before.

Keratin Coating—Keratin is made from corneous animal substances, like horn, quills, hoofs, etc., by steeping these in an acid solution of pepsin or acetic acid, and dissolving the residue in ammonia water and evaporating the solution. The coating is applied like sugar coating, but is rarely used today, since its solution, even in the intestinal tract, is quite uncertain.

CHAPTER CVI

SUPPOSITORIES

Suppositoria—*Suppositories*

Suppositories are solid bodies intended for insertion into the rectum, urethra, or vagina to produce medicinal action. A urethral suppository is also known under the name *bougie*, or *bacillum*, or *cereolus*. When for insertion into the nasal passages a similarly shaped suppository is called a *buginarium*. The usual form of suppositories is more or less conical, with a rounded apex (see Figs. 704 and 705). A variety of shapes will be noticed. The smaller are for rectal use and the Pharmacopœia directs that the adult *rectal suppository* shall weigh about 2 Gm. (30 grains) if made from oil of theobroma, or 4 Gm. (60 grains) if made from glycerinated gelatin. The *infant rectal* suppository is usually about one-half this weight. The larger, more or less globular form, represent *vaginal suppositories*, and officially shall weigh about 4 Gm. (30 grains) if made with oil of theobroma, or about 10 Gm. (150 grains) if made from glycerinated gelatin. The pencil-shaped suppositories represent *urethral* types, which, if made from glycerinated gelatin, are to weigh about 2 Gm. (30 grains) and be 7 cm. (2½ inches) long for female use, or weigh about 4 Gm. (60 grains), and measure 14 cm. (5 inches) if for a male urethral suppository. If a urethral suppository is made from oil of theobroma it should weigh about one-half the above quantity. Three types of suppositories, with respect to the vehicle or base used, are recognized; first, those prepared with *oil of theobroma* or cacao butter (more commonly called cocoa butter), as the diluent and vehicle, and which quickly melt to an oily fluid at the temperature of the body. The second type is prepared with a mixture of equal parts of glycerin and gelatin, known as *glycerinated gelatin* (see page 524), as the diluent and vehicle. This type of suppositories does not melt at the body temperature but slowly dissolves in the secretions of the mucous membrane. They are usually employed to provide a continuous medicating or germicidal action. The third type, represented by glycerin suppositories, or soap suppositories shaped from castile soap, is not expected to melt or dissolve but to perform its function largely mechanically, producing some irritation. Their chief value is as a stimulation to peristalsis, through their presence in the rectum and they are largely used for small children to produce a movement of the bowel, thus avoiding the use of a laxative.

Oil of theobroma is an ideal vehicle or base for suppositories intended to melt when inserted into the rectum or other body cavity. It was first suggested in this connection in 1852 by Alfred B. Taylor, of Philadelphia. It is a bland, non-irritating oil, pressed from ground cacao beans, and possessing the remarkable quality of maintaining its firmness, even exceptional hardness for a fatty substance, to within a few degrees of the body temperature, when it readily melts to a liquid, without passing through an appreciable softening stage. The melting point of oil of theobroma is from 30° to 35° C. (86° to 95° F.) (see also page 1040).

It is rarely necessary to raise the melting point of cacao butter by the addition of wax, spermaceti, etc., except in the warmest summer weather, or when phenol, camphor, chloral hydrate, the volatile oils, or similar substances form the medicating ingredients.

Oil of Theobroma Suppositories—To prepare suppositories with oil of theobroma as the vehicle or base, three methods are available in most phar-

FIG. 704

Shapes of suppositories (exact size) (Colton)

macies. The first is known as "hand made or rolled", the second, "molded", and the third, "machine made or pressed".

The details of these several processes follow:

Rolled or hand made suppositories represent the simplest process providing the climate or weather conditions make it applicable. In warm countries or

in hot summer weather one of the other methods should be used. This process possesses an advantage over the molding process in that no complications arise from the use of heat and no provision need be made for excess material, since the entire mass is divided into the desired number of suppositories.

The following general process may be employed:

The cacao butter is scraped or grated and usually kept on hand ready for use. The grater illustrated on page 156, Fig. 226, is especially well suited for this purpose.

Take the prescribed quantity of the medicinal substance and a sufficient quantity of grated *oil of theobroma*. Reduce the medicating ingredients to a fine powder, or, if composed of extracts, soften them with water and rub until

FIG. 705

Shapes of suppositories (exact size) (Colton)

a smooth paste is formed; the correct amount of grated oil of theobroma is then added, and a mass resembling a pill mass is made by thoroughly incorporating the ingredients with a pestle, usually with the aid of a small amount of expressed oil of almond, petrolatum, or best of all, wool fat. When the mass has become plastic under the vigorous kneading of the pestle it is quickly cut loose from the mortar with a spatula, pressed into a roughly-shaped mass in the center of the mortar and then transferred with the spatula, to the palm of the hand, which has been well dusted with an absorbent powder. By a quick, rotary movement, from the palm of the other hand, the mass is rolled to a ball which is immediately dropped to the well-dusted pill tile. Here a suppository cylinder is formed by rolling the mass upon the tile with a flat board, partially aided by the palm of the hand, if weather conditions permit. The length of the cylinder usually corresponds to about four spaces on the pill tile for each suppository, thus making the piece, when cut, practically a finished suppository except for the sharpening of the point. When the cylinder has been cut into the proper number of pieces with a spatula, the conical shape

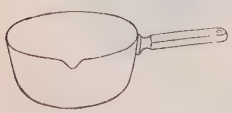
is given it by rolling *one end* upon the tile with a spatula, or in some cases even by shaping it with the fingers, so as to produce a rounded point. In warm weather it is necessary to use lycopodium, talc, starch, or a similar absorbent powder freely. With practice, excellent rolled suppositories can be made. This method has the substantial merit of requiring very little apparatus, but considerable skill is needed to produce suppositories equalling in finish those which are molded (see below).

One of the most rapid and efficient methods for shaping the finished suppository when the hand process is followed, is to roughly point the cylindrical section, which has been cut for an individual suppository, and force it quickly and with considerable pressure, applied by a spatula, or a roller board, into a cold suppository mold which has been well dusted with talc or lycopodium. Remove each suppository and again dust the mold before shaping the next one.

Molded Suppositories—If the suppositories are to be molded, calculate the amount of oil of theobroma required to make suppositories of the desired weight, taking into consideration the weight of the medicine to be incorporated, and also planning for enough additional medication and also oil of theobroma for at least one extra suppository. This is necessary to provide for the waste in pouring the suppositories; some mass always sticking to the dipper and other excess portions are usually being cut from the top of the mold and must be provided for.

Having finely powdered the medicinal ingredients, if vegetable drugs or chemicals, and having softened extracts when present, weigh the total amount of oil of theobroma needed and melt it in a dipper with a gentle heat. A porcelain casserole (see Fig. 706) is the best vessel in which to melt the oil of theobroma which must always be warmed on a water bath of lukewarm water. Incorporate the medicinal substances intimately with about an equal weight of the melted oil of theobroma, on an ointment slab, using a spatula and, when uniformly mixed, transfer the uniform mixture to the remainder of the melted oil of theobroma, which has been cooled to the correct temperature, which is almost that of the solidifying point. Stir until all is again uniformly melted and pour at once.

Fig. 706



Casserole

Pouring the Mass—The melted mass should be poured into the chilled mold from the dipper, which is usually held in the right hand. It should be vigorously stirred with a spatula immediately before the pouring begins; indeed, when heavy powders are directed, the stirring must not cease during the pouring, or the last suppositories will contain a larger proportion of the heavy powder than those which were first made. In pouring, each opening in the mold may be exactly and uniformly filled or the openings may all be overflowed so that the tops run together on the mold. In the latter case allow the molds to stand on the counter until the mass on top has solidified, then cut off the excess with a spatula. The molds are then placed on ice and when sufficiently hardened the suppository will be found to have contracted slightly so that light pressure on the base of each suppository will cause it to loosen in the mold and readily drop out when the mold is opened. If the suppository does not readily drop from the mold after they are opened, apply a quick, firm pressure with the thumb, first to the base and if this does not free it try pressing the point. Never apply continued pressure. It will melt the suppository. It is also desirable to cool the thumb, by placing it on the ice for a moment, before giving the quick, firm pressure. The novice almost invariably

makes the mistake of opening the divided molds too soon (before the limit of contraction is reached); the suppository sticks to the mold, and splitting ensues.

Some pharmacists prefer to use a lubricant in the molds to facilitate the removal of the suppositories. Lycopodium and also a 6 per cent solution of castile soap or of soft soap, in 70 per cent alcohol are used. The soap solution is best applied by twisting cotton on a match stick and using just sufficient solution to moisten the walls of the mold. The alcohol must evaporate before pouring the mass. Lycopodium is considered by some to be objectionable because of its alleged irritation to mucous membrane.

The beginner often fails when starting with the fusion method due to the use of too much heat. When it is to be remembered that an oil of theobroma suppository mass melts at the temperature of the body and that the least possible heat should be used, the dispenser soon learns to keep away from a direct flame entirely and only use a lukewarm water bath.

Many combinations are decomposed or separated from the base by overheating. This is notably the case with ichthyol or with mixtures of astringent drugs and vegetable extracts, such as lead acetate or tannic acid with the extracts of opium, belladonna, stramonium, etc.

Ingredients which soften Oil of Theobroma—Suppositories containing chloral hydrate, phenol, or other substances which soften the vehicle, should have the melting point of the oil of theobroma slightly raised by the addition of from 10 to 15 per cent of spermaceti, but the melting point must not be above 37° C. (98.6° F.).

Other difficulties in molding suppositories are easily overcome by the exercise of judgment and knowledge of physical laws. A defect frequently seen in the finished cacao butter suppository is that the surface is not always perfectly smooth. This may arise from several causes. Sometimes ridges are seen traversing the suppository; these are usually produced by overcautiousness, the operator pausing in pouring the melted mass into the mold, then pouring in a little more, then pausing again, and so on. On taking out the suppository, a ridge will be found at each spot where a pause was made. The remedy for this is to keep on pouring steadily when this part of the process is reached. Other defects are pitting, causing an imperfection in points of the suppositories. This pitting is usually caused by drops of water which have not been shaken out of the mold before pouring in the melted mass. Still another defect is a depression in the center of the base of each suppository. This is due to not overflowing the molds so as to leave an excess of mass upon the top and it is intensified by pouring the mass when too warm. In all cases there should be a little more mass than will fill the molds; after cooling the excess may be cut off.

If strong heat is used upon an extract mixture ready to be molded, water is evaporated, the extract separates in small masses, and, like a bad emulsion, the mass is "cracked". The remedy is to pour it at once upon an ointment slab or tile, add a little water, and rub it until the original condition is regained. However, as has already been emphasized, the mass containing the medicating ingredients should not be heated directly. Heat should be applied only to the oil of theobroma.

The shape of the suppository marked "15", in Fig. 704, was devised by Henry S. Wellcome, of London. It is intended to prevent the expulsion of the suppository after insertion and is a notable improvement over the conical type.

Glycerinated Gelatin Suppositories—The basic material from which suppositories are made is official (see page 524). They are used chiefly for

vaginal suppositories and are mostly healing or germicidal. Boroglycerin, ichthyol, zinc oxide, and bismuth subnitrate, are typical forms of medication. They may be made by mixing the medicinal substance, if solid and soluble, in water or glycerin, or if a miscible liquid, with a little water, and adding sufficient glycerin to make the weight of the mixture one-half that of the finished mass; then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it at once into suitable molds which have been greased with a small quantity of petrolatum. Cool the molds thoroughly before removing the suppositories. Molds for urethral suppositories should be warmed sufficiently before pouring the mass to facilitate the proper filling of the mold. Suppositories having a firmer consistence may be prepared by substituting mucilage of acacia for a portion of the water or glycerin.

If the medicinal substance is insoluble in water or glycerin, thoroughly levigate it in a warm mortar with a sufficient quantity of glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted glycerinated gelatin, and pour it into suitable molds as above directed. With bulky powders about one-half of the glycerin may be replaced with water before levigation.

Glycerinated gelatin suppositories should be protected against the effects of heat, moisture and dry air by keeping them in tightly-closed containers in a cool place.

Suppository Molds—Many forms are in use.

Individual molds are those which were first employed but they have been largely replaced by more efficient forms. Fig. 707 illustrates the type. The difficulty of quickly and easily removing the suppositories, the trouble in cleaning them, and the liability of losing or misplacing them, constitute the most serious drawbacks to the use of this form.

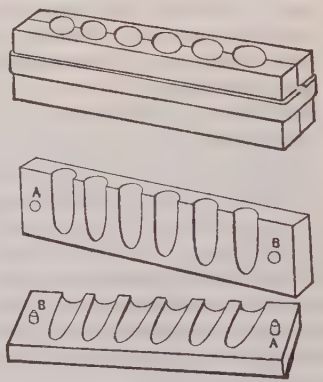
Individual molds for vaginal suppositories may be obtained and are of value in the prescription department.

The earliest form of divided mold is illustrated in Fig. 708. An elastic band holds the

Fig. 707

Individual suppository molds

Fig. 708



Divided suppository molds

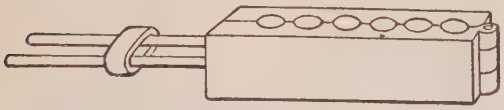
sections together but the hinged mold is better and has almost entirely replaced it.

Round molds were at one time used. The See's mold and also Blackman's were well known forms but they are almost entirely replaced today by hinged molds.

One of the simplest forms of the hinged mold is seen in Fig. 709. This opens at the end. Another form of hinged mold, largely used today, is constructed so that two different sizes of suppositories may be made in it (see Fig. 710). Fig. 711 illustrates a very serviceable English mold, recommended by Mr. Henry B. Brady, of Newcastle-on-Tyne. It differs from others in being hinged at the bottom. It is held together by two screw catches,

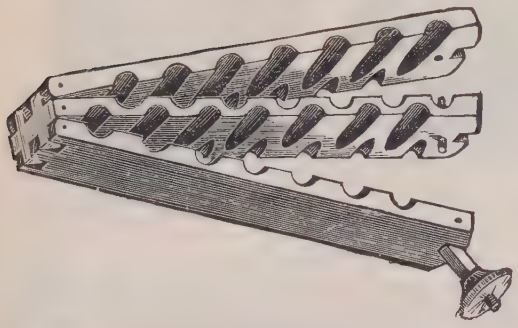
one at each end. Fig. 712 shows the usual manner of chilling suppository molds. It is desirable to place the mold on a piece of thin paper and then on the ice, to avoid the seepage of water into the molds. Fig. 713 shows

Fig. 709



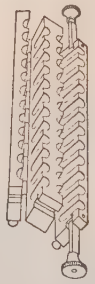
Hinged suppository mold

Fig. 710



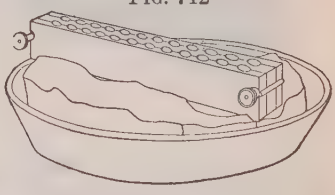
Two-size suppository mold

Fig. 711



Brady's suppository mold

Fig. 712



Brady's suppository mold on ice

Colton's mold for making glycerin suppositories. The manner of using it is similar to that of the preceding molds. It makes a double pointed suppository, as shown in the illustration. Molds for making gelatin suppositories

Fig. 713

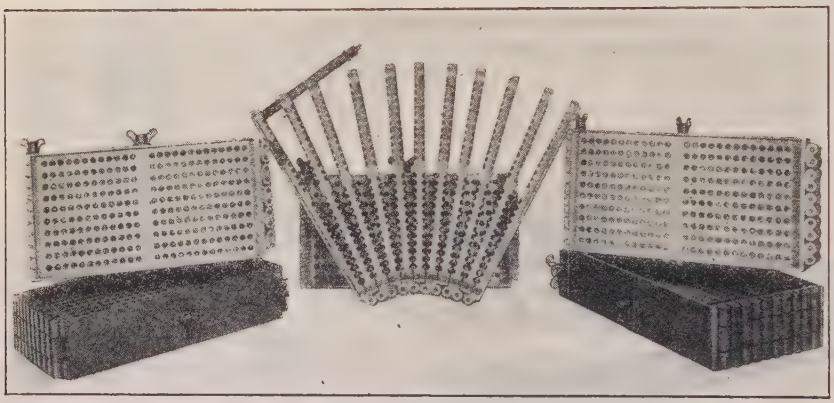
Colton's glycerin suppository mold

with a rounded end, as shown in Fig. 713, are also made by Arthur Colton, of Detroit. In Fig. 714 is shown the Stokes' suppository mold for making a large number of suppositories at one filling.

Compressed Suppositories—The compression method for making oil of theobroma suppositories is now used in many pharmacies. Some of the earlier types such as Knowlson's, Archibald's and the "Rapid Fire" suppository machine have been replaced by the machines illustrated.

A small compression machine for making individual suppositories is illustrated in Fig. 715. This is sold by the William S. Merrell Company. The

FIG. 714



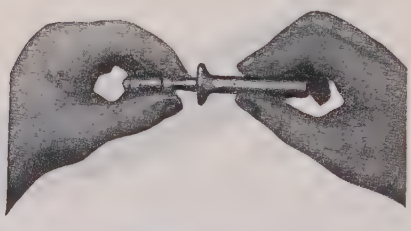
Stokes' suppository molds

mass is prepared as already described and the machine used in the mortar like a pestle. The material is forced into the suppository-shaped mold in the end and, when full, the suppository is removed by twisting out the metal collar which brings the suppository with it. The top of the machine is so

FIG. 715

Filling Merrell suppository mold

FIG. 716



Ejecting suppository from Merrell mold

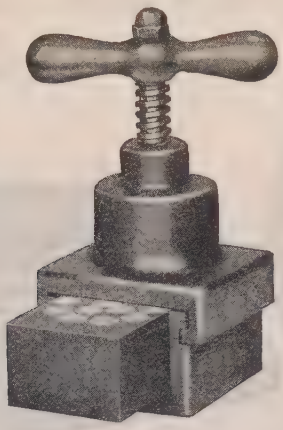
shaped that it can now be used to push the finished suppository from the collar (see Fig. 716). Then the collar is slipped back into place and the next suppository made.

The Applebaum Suppository Machine (see Fig. 717), manufactured by the Druggists' Appliance Manufacturing Company, is made of aluminum and is furnished with molds for infant and adult rectal suppositories and also for vaginal suppositories. The plunger is turned to the highest point and the prepared mass packed in the cylinder. Then the desired mold is slipped into

place and the handle turned down until the molds are filled. The plunger is then released and the mold taken out and opened.

The Whitall Tatum Company furnish the machine shown in Fig. 718. It consists of a cylinder, which can be removed to receive the charge of

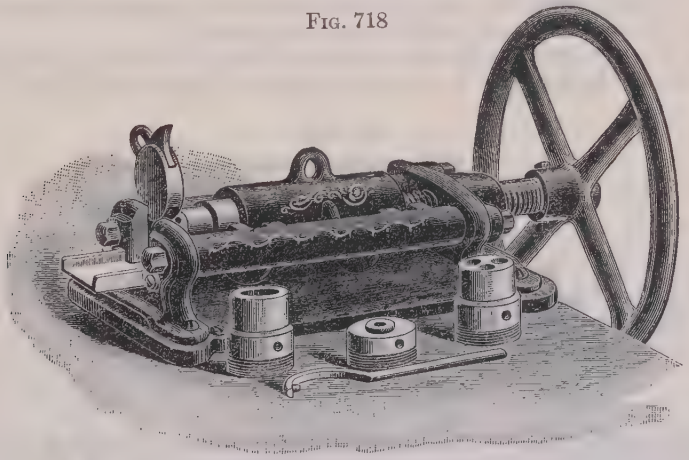
FIG. 717



Applebaum suppository machine

suppository mass, the proper mold having been previously screwed into place. The cylinder is then returned to its position, and, the gate having been closed, pressure is made by turning the wheel. The gate being then lifted, a slight pressure suffices to force out the suppositories. Repeating the operation,

FIG. 718



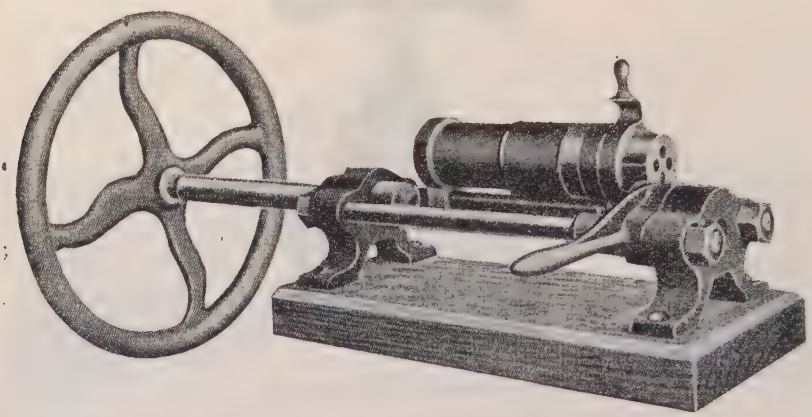
Whitall Tatum suppository machine

it is obvious that the machine will turn out suppositories as long as any mass remains in the cylinder. Brass dies and a tube are furnished to make 15 grain, 30 grain, vaginal, urethral, or nasal suppositories. Urethral or nasal suppositories are made by screwing on the proper die and then pressing the mass through it. A long rod-like suppository is thus forced out, which may be cut into suitable lengths.

Similar suppository machines are also sold by Arthur Colton and by the F. J. Stokes Company (see Fig. 719).

In making *ichthyol suppositories* by compression, the addition of 5 per cent of heavy magnesia will be found helpful in the making of a firm mass. At least 10 per cent of ichthyol may be incorporated by this method. By evaporating the ichthyol carefully larger amounts can also be incorporated.

Fig. 719

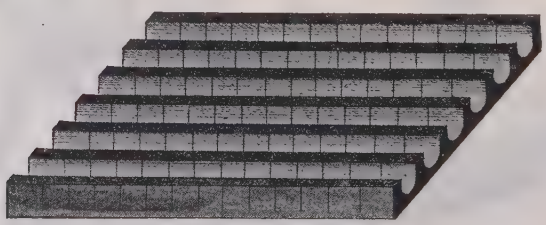


Colton's suppository machine

Nicolaus Drugocin, a prescription pharmacist associated with Leonard A. Seltzer, of Detroit, devised an outfit for preparing rectal suppositories by the use of a urethral mold, in a compression suppository machine, which delivers a continuous pencil shaped rod of suppository mass.

This rod or cylinder is cut into lengths of about 15 inches, and each one is laid in one of the troughs in the special board illustrated in Fig. 720. The

Fig. 720



Board for cutting suppositories

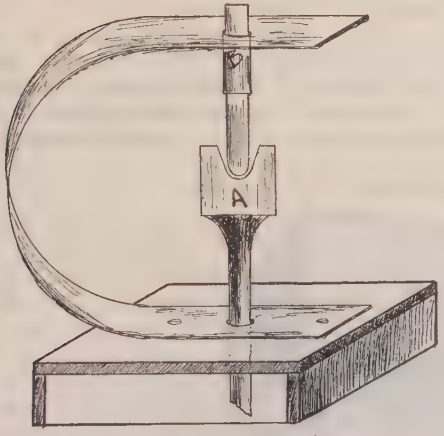
cylinders are now cut into uniform lengths by running a spatula through the kerfs, and the resulting short cylinder is rounded at one end, forming a suppository. The piece of apparatus (Fig. 721) is used by Mr. Drugocin for shaping the point. The cylinder is slipped into *B* and the cone "*A*" is made to spin rapidly by attaching a belt from a small motor, until the rounded point forms.

Fig. 722 shows Colton's power suppository machine. It is adapted for making suppositories upon a large scale, one hundred suppositories being made at a time. It is fitted with a device for cooling the mass in hot weather,

the cylinder in which the mass is placed being surrounded with a jacket for holding iced water.

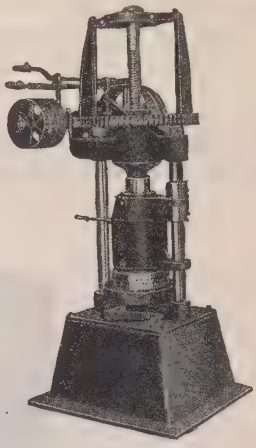
Suppositories are sometimes introduced into the rectum with difficulty.

FIG. 721



Shaping suppository point

FIG. 722

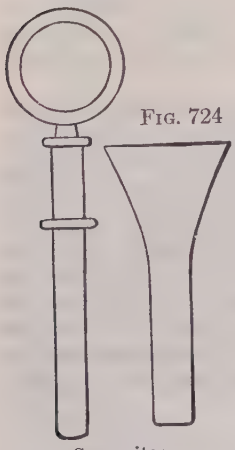


Colton's power suppository machine

Figs. 723 and 724 show a suppositor to aid in their insertion. The tube is made of hard metal, and has a funnel shaped top (Fig. 724). The suppository is dropped into the tube (which should be slightly oiled), point downward, and

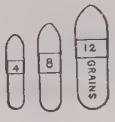
FIG. 723

FIG. 724



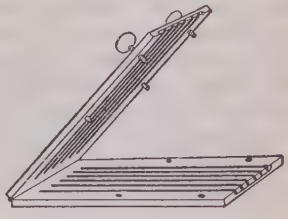
Suppositor

FIG. 725



Suppository capsules

FIG. 726



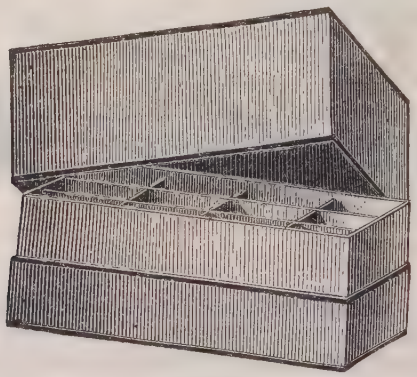
Bougie mold

the tube is carefully inserted into the rectum. The piston (Fig. 723) is now applied to the end of the suppository, which is gently pushed into the rectum, the tube being then withdrawn. A similar device, made of hard rubber, is sometimes used for the insertion of urethral suppositories.

Suppository Capsules—Dr. F. E. Stewart has suggested the employment of gelatin shells with conical caps, to be used as suppositories. The medicating ingredients are inserted in the lower portion. The upper margin is then moistened with water, and the cap inserted. Before introducing them into the rectum they should be wet with sufficient water to enable them to slip in easily (see Fig. 725).

Urethral Suppositories or Bougies, are preferably made of gelatin, owing to the difficulty of introducing into the urethra those made from cacao butter, on account of their brittleness. They may be made by melting together three parts of gelatin, one part of glycerin, and one part of distilled water, by weight, then adding the desired medicament and drawing the mass into a glass tube of suitable size, which has been previously oiled by sucking a small quantity of

FIG. 727.



Suppository box

oil into it and allowing it to run out. After cooling, the mass is pushed out by means of an oiled rod, and cut into pieces of suitable length. These should be rolled in lycopodium to prevent adhesion. Fig. 726 shows a bougie mold for making them in quantity.

Dispensing Suppositories—In order to prevent injury to the surface of suppositories in handling them with warm fingers, it is advisable to place the finger tips for a few moments upon ice until they are chilled, before placing the suppositories in the box. The latter is preferably furnished with partitions (see Fig. 727). In the absence of this special box, the suppositories should be protected by a layer of cotton or each suppository may be tightly wrapped with paraffin paper or with tin foil, with the end twisted. If properly applied the paper, and especially the tin foil, forms a temporary mold about the suppository and it cannot readily collapse, even in warm weather. When the suppository is to be used it may be held by the twisted end, dropped into ice water until thoroughly chilled, the wrapping removed, and the suppository inserted.

CHAPTER CVII

SOLID EXTEMPORANEOUS PREPARATIONS USED EXTERNALLY

Cerates, Ointments, and Pastes

Unguenta—*Ointments*

Ointments are fatty preparations, of a softer consistence than cerates, intended to be applied to the skin by inunction. The medicating ingredients are combined with a vehicle of lard, petrolatum, wool fat, or similar substance. Ointments are made in several ways: 1. By fusion. 2. By incorporation. 3. By chemical reaction. The official formulas for ointments will be found on pages 502 to 511.

1. **By Fusion**—In making ointments in this way, care must be observed not to apply sufficient heat to burn the constituents. Cerates and ointments may be strained through flannel or muslin to separate mechanical impurities, or some may be filtered. (See page 205.)

2. **By Incorporation**—The method of making ointments by incorporation is more frequently used than any other. The medicating ingredients used are nearly always insoluble in the basis, and it is necessary, therefore, to reduce them to a fine state of division in order to facilitate their absorption or medicinal action. The usual mode of procedure is to place the fatty basis upon an ointment slab, and the medicating substance close by. The latter, if in fine powder, is first mixed with a *small portion* of the basis by rubbing both backward and forward with the blade of a spatula until the mixture is perfectly smooth. It is then a very simple operation to dilute this small quantity of concentrated ointment by incorporating it with the rest of the basis, by using the spatula in the same way. If extracts are to be incorporated, they are softened by adding a little water or diluted alcohol, until a smooth paste is made, which is then worked into the basis with a spatula. Many other medicinal ingredients beside extracts may be rubbed with a liquid to aid their incorporation with the fatty vehicle. These fall into four general classes as follows: 1. Those cases in which the liquid dissolves the medicament and then combines with the fat as when menthol is dissolved in a little liquid petrolatum and then mixed with the base. 2. It may be that the liquid will not dissolve the medicine and is only miscible with certain fatty vehicles. This was illustrated in the former method for making ointment of yellow mercuric oxide when the oxide was rubbed with water and this mixed with wool fat. 3. In another case the liquid may dissolve the added medication, be miscible only with certain fatty bases, as when cocaine hydrochloride is dissolved in water and then incorporated with wool fat or a wool fat mixture. 4. In a fourth case the liquid may but form a paste which may be uniformly incorporated with the fat. The softening of vegetable extracts is an illustration.

Ointment Slabs—An excellent ointment slab is made by setting a plate of ground glass in a wooden frame or slide or even better by securing a piece of skylight glass, about two feet square and over an inch in thickness and having one surface ground until smooth. Such a slab was suggested by Samuel L. Hilton, of Washington, D. C., and has been to him and others a great source of satisfaction in making ointments at the prescription counter both because of its unusual size and also because of its weight which holds it firmly in

place while rubbing the ointment. Ointments are sometimes made in a mortar with the pestle; but this method is less convenient.

In incorporating ointments containing substances which act on steel, rubber spatulas may be used (see Figs. 217 and 218). When large quantities of ointments are required to be made by incorporation, the usual custom is to use a power-driven paint mill in which the ointment, which has been roughly mixed, is subjected to continuous rubbing between iron disks for an extended period, it gradually working its way to the outer edge of the disks, from which it is scraped. Fig. 727a illustrates a Stokes ointment mill. Ointments are sometimes made on a large scale in pot mills (see Fig. 230).

3. **By Chemical Reaction**—The only official ointment that is made by chemical reaction is the ointment of mercuric nitrate. In this, the olein of the lard is converted into elaidin through the action of heat and nitric acid; solution of mercuric nitrate is then incorporated with the elaidin vehicle.

Maxims to be Observed in Making or Dispensing Ointments—1. They should never be dispensed if they have the slightest taint of rancidity. 2. They

Fig. 727a

Ointment mill

Ointment jar (amber glass)

Fig. 728

Porcelain jar

Fig. 730

Ointment pot

Fig. 731

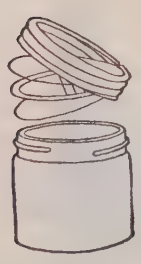
Ointment pot

should always be smooth and free from grittiness or irritating particles. 3. Ointments containing free acid, iodine, or tannin should not be rubbed with an iron or steel spatula, on account of the chemical action on the metal. 4. In removing the ointment from a stock jar always scrape it from the surface. Never dig into it, as holes left in the surface tend to increase rancidity.

Preserving and Dispensing Ointments—Animal or fatty substances may be preserved from rancidity by digesting them with balsamic resins, benzoin, poplar buds, styrax, etc. To preserve them during hot weather, they require in addition a cool temperature and freedom from exposure to the air. When a fresh lot of ointment is made to replenish a stock jar, the jar should be thoroughly cleaned, and the old ointment remaining thrown away, unless it is certain that the latter is entirely free from rancidity, as otherwise it would soon cause the new ointment to become rancid. Amber glass, stoneware or porcelain jars are the best receptacles for ointments. Fig. 728 shows a porcelain jar, which is just as useful for preserving ointments as it is for holding a penetrating substance like green soap. Fig. 729 illustrates an amber glass stock ointment jar made by the Whitall Tatum Company. The letters for the label are

blown in the glass, and then ground off, so that the label is indestructible. The only difficulty is that the label requires a strong light to enable it to be seen clearly. For dispensing ointments the opal glass pot is very useful. The best shapes are shown in Figs. 730 and 731. The bottom is rounded, so that the patient can easily reach all the ointment with the finger, and the top is metallic, with a screw cap. There is room for the label on the glass. Fig. 732 shows an ointment pot which is fitted with a metallic screw cap; the round label has a transparent celluloid disk above it and a heavy waxed disk below it, the whole making a greaseproof top to the pot. Of the very cheap boxes, those turned from wood are totally *unfit* for dispensing ointments. The ointment quickly penetrates through the grain of the wooden bottom, and the greasy abomination is exceedingly unwelcome to most housekeepers. Tin boxes are frequently used for small quantities of ointment sold to the layman and screw top wide-mouthed glass jars are also

Fig. 732



Sterling ointment pot

Fig. 733

Upressit pot (to close)

Fig. 734

Upressit pot (to open)

employed. The impervious walnut boxes, made by gluing several veneers of hard wood together, are still better. Figs. 733 and 734 illustrate the "*Upressit*" ointment pot which may be readily opened or closed by pressing the center or outer edge of the lid respectively. It is made by the United States Metal Cap and Seal Company of New York.

Collapsible Tubes—A marked improvement in the method for the dispensing of ointments is now in general use. The method in use for many years has been to introduce the ointment in a pot or jar having a slip or screw lid. An ointment in such a container is frequently exposed to dust and is almost invariably removed from the jar, as used, by means of the finger. Both of these conditions are undesirable and unsanitary. In addition, the jar method of dispensing constantly exposes the ointment, over an extended surface, to the action of the air and frequently to the action of light, and this greatly hastens evaporation in the cold cream type of ointments, making them unfit for use, and also promotes rancidity in the fatty vehicles used if these are of animal or vegetable origin.

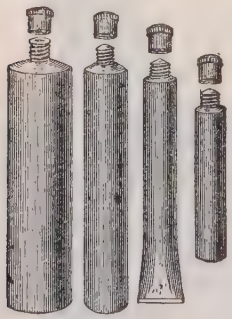
The modern plan, *i.e.*, dispensing ointments in pure tin, collapsible tubes, (see Fig. 735) avoids all of the serious defects of the jar method and at the

same time costs no more and the ointment is just as easily handled. Emphasis should be placed upon the use of pure tin tubes, as those made from composition metal are more readily attacked by certain ingredients which may enter ointments. For iodine-containing ointments a tube made of celluloid is also now available.

For eye ointments, tubes, with nozzle-like outlets, are obtainable which facilitate the application of the ointment and other special forms, fitted with nozzle-like ends, permit the dispensing of ointments for application to either the nasal passages or to the rectum.

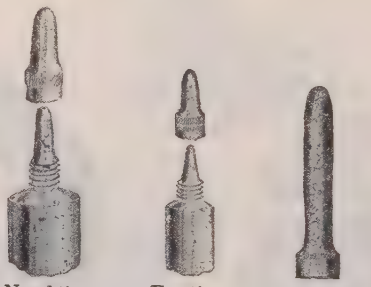
In filling the tubes with a soft ointment in prescription work, a method which has given much satisfaction because of its cleanliness, rapidity, and simplicity is as follows: Place the finished ointment in the center of a piece of manila or other strong paper of sufficient size (for an ounce of ointment use a sheet about 8 by 10 inches), fold it over so that the edges meet, with the ointment inside, place a pencil on the top fold on a counter, and, holding the under sheet, slowly roll the pencil toward the ointment. This causes it to form into a cylinder, and, when this is of a less diameter than the tube, roll

Fig. 735



Collapsible tubes

Fig. 736



Special tips for collapsible tubes (One-half actual size)

this cylinder over on the remainder of the paper so as to form a paper tube with the ointment inside. Now slip this into the collapsible tube and start to fold over the protruding end of the paper tube. When the ointment has thus been forced completely into the metal tube, bring the edges together by flattening the open end and, with the tube resting upon a firm surface hold the flattened edges together firmly with the index finger of the left hand and slowly withdraw the paper with the other hand. This leaves the ointment inside and the tube is ready to close permanently. It has also been suggested that the paper be cut off and left inside the tube, but its withdrawal seems preferable. The cap end of the tube should be open during this process of filling and closing.

In closing a tube, care must be taken to see that it is not filled too full; it should be folded over at least twice.

The capacity of each size of tube can be readily ascertained by a trial with petrolatum and this information may then become a permanent record for the prescription department.

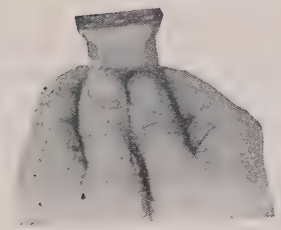
Special pliers for closing tubes are obtainable at small cost; a check cancelling machine of the type which causes numerous small cuts in the check when stamped over the written numerals has been recommended for closing and is very satisfactory, but the back of a heavy table knife is quite as effective

as the more expensive devices. In using a knife or stiff spatula, hold the filled tube in the left hand on a counter with the open end to the right, run the knife lightly along the tube to slightly flatten it, when near the end increase the pressure and, when within a quarter of an inch from the opening, hold the knife firmly and raise the tube, laying it over upon itself. Repeat this a second time and the tube is closed.

For satisfaction to the customer, in the use of tubes for ointments a hard metal clip should be clamped over the fold to prevent the contents being forced from the folded end when pressure is applied to the tube (see Fig. 737). These clips are very inexpensive and may be readily attached with the aid of a small bench vise, although many forms of machines are also available for the purpose.

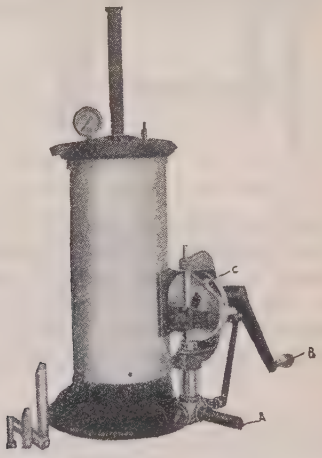
One difficulty always experienced is in the labeling of the tubes. If the label is to be attached, the tube may be dipped in compound tincture of ben-

Fig. 737



Tube closed with clip

Fig. 738



Tube filling machine

zoin or in a regular lacquer and afterwards allowed to dry. This will facilitate labeling and it is always desirable, if labels are applied, to use them in strip form so as to completely encircle the tube and prevent their coming off. Solution of sodium silicate has also been used on the tube and will cause the labels to stick. At best, however, labels are not very satisfactory, as the tube is likely to be completely rolled upon itself as the last of the ointment is used and the label soiled or destroyed, so that some pharmacists are using a paste-board box to hold the tube and carry the label, while the tube itself is stamped in the tin with the prescription number, using a numbering machine. This will permit the identification of the prescription and its renewal, even if the box is lost.

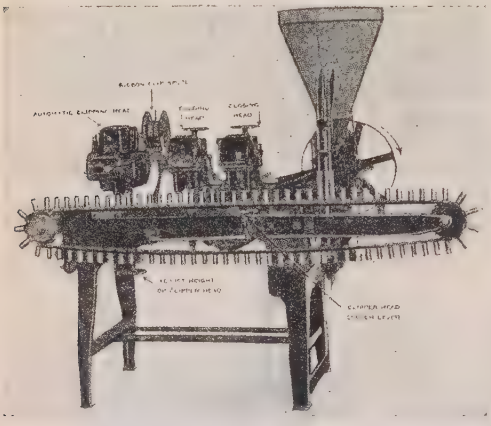
Figs. 738 and 739 illustrate machines made by the Arthur Colton Company of Detroit for filling and closing collapsible tubes. Such substances as ointments, tooth paste, etc., are rapidly and automatically handled by the larger machine and the smaller one is semi-automatic. Similar machines are made by the F. J. Stokes Company of Philadelphia.

Fig. 740 shows Alper's ointment filler. It consists of a tin kettle surrounded

by a water bath, in such a way that the liquid ointment can easily be drawn through the stopcock. Small boxes, bottles, or collapsible tubes can quickly and easily be filled with petrolatum, ointment, or similar preparations, without the inconvenience of handling them in spoons or ladles.

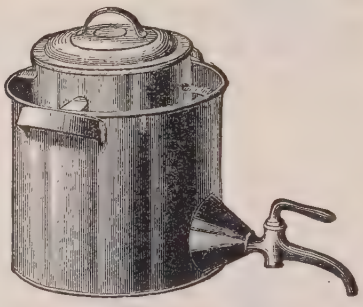
Finishing Ointment—Some skill is required to fill a box with ointment neatly and deftly by using a spatula without soiling the exterior of the box.

FIG. 739



Tube filling and closing machine

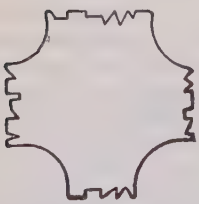
FIG. 740



Alper's ointment filler

The surface should be slightly lower than the edge of the jar to prevent the lid from tarnishing. This is accomplished by holding a spatula at a slight downward angle, with its tip at the center of the jar and its edge resting on the jar. By slowly rotating the jar an even depression is formed. It may then be held near a hot surface, like a stove plate, or may be played upon for a moment by a Bunsen flame, to give it a gloss. Occasionally it will be found

FIG. 741



Ointment finisher

FIG. 742

Finishing ointment

that some nervous patients desire to be assured that an ointment or cerate has not been tampered with by a servant, and it may be desirable for other reasons to finish the surface of an ointment with a distinctive design. This may be done by cutting a piece of tin into a shape similar to that shown in Fig. 741. By placing one of the teeth on the edge of the pot (see Fig. 742), and slowly rotating it, with alternate pauses, a very neat finish may be given to the surface. The finisher (see Fig. 741) shows four sides, and is of course capable of making four patterns.

CHAPTER CVIII

PLASTERS AND PAPERS

Emplastra—*Plasters*

Plasters are substances intended for external application, made of such materials and of such consistency as to adhere to the skin.

The base of the older form of plaster was a compound of litharge and oil. This was known as diachylon plaster and in a modified form is still employed. This type of mass requires the application of heat in spreading and in applying the plaster to the skin. Emplastrum Plumbi Oleatis or lead oleate plaster is of this type. Such a plaster mass has now been largely supplanted by a plaster made with a base of gum caoutchouc.

India rubber plaster mass, according to the nature of the plaster and its purpose is a compound of gums, such as galbanum and olibanum, with waxes, fats and excipients such as Burgundy pitch, together with proper medication, incorporated to complete the mass. The making of the India rubber plaster mass requires the use of extensive apparatus for the grinding and preparation of the rubber and gums, and the mixing of the mass and the final spreading upon cloth.

The lead and resin type of plaster mass must be heated in order that it may adhere to the skin. On the contrary, plasters made with an India rubber base are adhesive at the temperature of the body, hence ready for application without further treatment. The plaster mass, while adhesive, can be removed without the disturbance of the skin tissues.

EMPLASTRUM ADHÆSIVUM. U. S. Adhesive Plaster

[**Emp. Adhæs.**—Emplastrum Elasticum U. S. P. IX, Rubber Adhesive Plaster]

A mixture of rubber, resins, and waxes, with a filler of an absorbent powder, such as zinc oxide, orris root, or starch, mechanically mixed and spread upon cotton cloth (see page 518).

A strip of the Plaster 5 cm. by 6.5 cm. applied to a hard wood surface for thirty minutes at a constant temperature of 37° C. should resist a tension of not less than 40 pounds when applied by a tensile strength or other suitable device, the pull being exerted parallel with the warp and with the longer dimension of the Plaster.

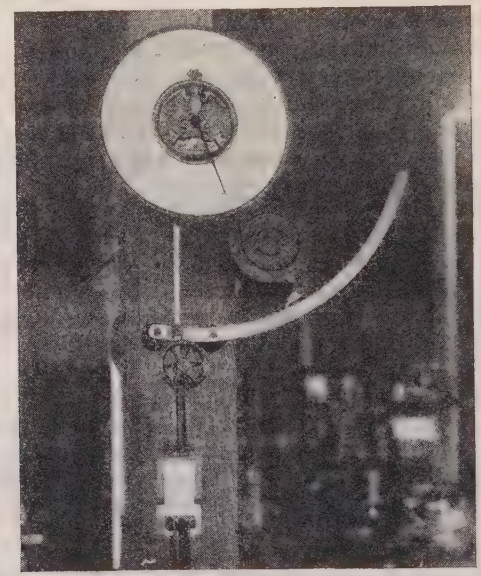
An instrument suitable for determining the tension-resistant quality of adhesive plaster is shown in Fig. 743. A strip of plaster 5 cm. by 6.5 cm. is kept at a temperature of 37° centigrade for thirty minutes, and then applied to blocks of wood, as shown in the illustration, and traction applied. The plaster should resist a tension of not less than forty pounds. It is made by Henry L. Scott and Company.

The use of the general term "adhesive plaster", without qualification, is apt to lead to confusion, there being several official and non-official plasters to which this name is applied. In modern practice, however, unless a more specific type is named, the term "adhesive plaster" is intended to apply to the adhesive plaster made with a rubber base.

Adhesive plaster made with a rubber mass is supplied in two types, one of which is known as *surgeons' adhesive plaster*. This is a plain mass of a yellow color. The second type is of a white color containing oxide of zinc and is the

kind usually required. It is known as *zinc oxide adhesive plaster*. Adhesive plaster made with a rubber base for mechanical use is spread on plain muslin, likewise on the so-called moleskin cloth, and also on felt. The plaster is supplied in rolls, one and five yards long, and of a width up to seven inches, also in rolls five yards long and twelve inches wide. It is likewise prepared in narrow widths, on spools, and in cylinder form, of varying lengths and widths.

FIG. 743



Tensile strength machine

EMPLASTRUM BELLADONNÆ. U.S. Belladonna Plaster

Belladonna Plaster contains extract of belladonna, corresponding to not less than 0.25 per cent and not more than 0.30 per cent of the alkaloids of belladonna leaves.

(For assay see page 518.)

Uses—An anodyne application in rheumatic and neuralgic pains.

EMPLASTRUM CANTHARIDIS. U.S. Cantharides Plaster

(For formula and standards see page 519.)

Uses—Employed in appropriate size to produce a blister.

EMPLASTRUM CAPSICI. U.S. Capsicum Plaster

(See page 519.)

Uses—A rubifacient.

EMPLASTRUM PLUMBI OLEATIS. U.S. Lead Oleate Plaster

(For formula, history, etc., see page 519.)

Uses—A protective also used as a base for other plasters.

EMPLASTRUM SINAPIS. U.S. Mustard Plaster

For description, standards and tests, see page 520.

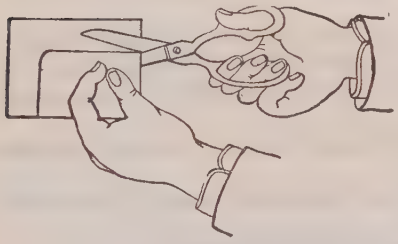
Before Mustard Plaster is applied, moisten it thoroughly with tepid water.

Uses—A rubifacient. A common substitute for the manufactured mustard plasters is the *mustard poultice* of the home, usually prepared by mixing equal parts of ground mustard and flour, moistening with tepid water to form a paste and applying to the skin in a muslin bag.

For N. F. plasters, see page 520.

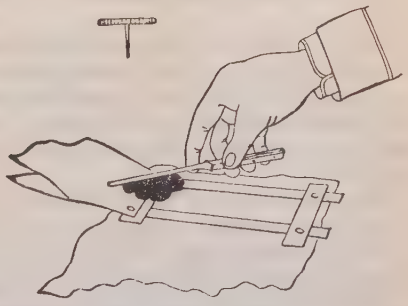
Dispensing Plasters—Since the introduction of machine spread plasters, the preparation of a plaster by a pharmacist upon the prescription of a physician has become almost a lost art. Lead base plasters are prepared for use by spreading them upon leather, muslin, paper, or adhesive plaster. A margin about a quarter or half an inch broad should usually be left uncovered, in

Fig. 744



Cutting plaster paper

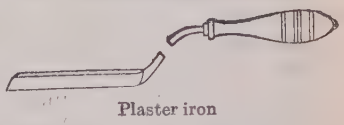
Fig. 745



Spreading a plaster

order to facilitate the removal of the plaster and to prevent the clothing from coming into contact with its edges. An accurate outline may be obtained by pasting, or fastening with thumb tacks, upon the leather, a piece of paper so cut as to leave in the center a vacant space of the required dimensions. The margin is to be removed after the plaster has been spread. To cut the pattern the paper is folded four times and cut as shown in (Fig. 744). The spreading of the plaster is most conveniently accomplished by the use of a spatula or plaster iron. This may be heated by means of a Bunsen burner. A sufficient portion of the plaster should be melted, then transferred to a piece of stiff paper, or shallow tin tray, open on one side, and when nearly cool, spread on the leather, quickly and evenly. Fig. 745 shows one method of spreading a small plaster with a spatula. Strips of paper are fastened upon the backing with thumb tacks (such as are used by draftsmen), as shown in the upper part of Fig. 745, a piece of waste paper is fastened at the top to prevent soiling the margin, the melted plaster is poured upon it and spread by the spatula, which has been previously warmed. A portion of the melted plaster precedes the blade in its passage, and thus a thin layer is spread upon the fabric. For large plasters the plaster iron (Fig. 746) may be employed.

Fig. 746



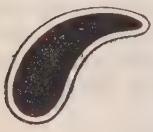
Plaster iron

Blister plasters do not usually require the application of heat to spread them. As a rule they may be spread upon the fabric by the aid of a stiff spatula.

The dispensing of plasters made with an India rubber mass consists, in the main, of the cutting of the plaster to the required shapes.

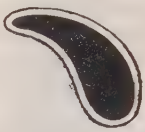
Rubber base plasters can be cut with a sharp knife, if the blade is dipped in water before cutting. Long sharp shears are preferable to small scissors, and the plasters will cut more readily if the shears are wet. It is a good practice to outline the size and shape on the plaster cloth with a pencil,

Fig. 747



Left ear plaster.

Fig. 748

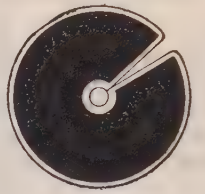


Right ear plaster

Fig. 749

Breast plaster pattern

Fig. 750



Breast plaster

then cut to the line. Square corners on a plaster should be trimmed or rounded off, as the corners are apt to rub loose.

Plasters for the chest, shoulder, back, and side, can be cut from the ordinary porous plaster made from a piece of plaster about 5×7 inches. Ear plasters can be cut from the small pieces, and breast plasters from a seven inch roll.

The illustrations, Figs. 750 to 754, show shapes which are applicable either to lead base or India rubber base plasters.

The following sizes were suggested by Dr. Rudolph Kobert (Director des Pharmacologischen Institutes zu Dorpat).

Half sheet paper size: Rectangular about $7\frac{1}{2}\times11\frac{7}{8}$ inches.

Fig. 751

Shoulder plaster

Fig. 752

Back plaster

Fig. 753

Side plaster

Fig. 754

Chest plaster

Quarter sheet paper size: About $5\frac{7}{8}\times7\frac{1}{2}$ inches. This is also known as size for trunk. An ordinary perforated (porous) plaster is very near this size.

Playing card size: $2\frac{1}{2}\times3\frac{1}{2}$ inches.

Size for surface of man's hand: $3\frac{1}{2}\times3\frac{1}{2}$ inches.

Size for neck: $2\times\frac{3}{8}$ inches.

Size for arms: $1\frac{1}{2}\times2$ inches.

Size for calves: $2\frac{1}{4}\times4$ inches.

Size for temples: $\frac{3}{4}\times1\frac{1}{4}$ inches.

Plasters, with India rubber as the base, retain their adhesiveness for a long time when preserved with proper precautions. These precautions are:

Plasters in rolls keep best standing on an end in the can or other container as they come from the maker. After use they should be replaced at once. This will obviate errors and enhance their chances of keeping more perfectly.

Cut plasters should always be kept in the original boxes with the cover closed. The plaster should always be kept covered with the face cloth. The

plaster should be kept at ordinary temperature, excluded from the air as much as possible, in a dry place, never in the cellar or in any place where they are apt to gather moisture.

India rubber plasters are quickly and disastrously affected by heat and by sunlight.

Many forms of medicated plasters are supplied by the manufacturers cut to a size of five by seven and one-half inches, with a face cloth and a back cloth made porous.

The porosity is considered a mechanical advantage in that it prevents the plaster from slipping from the point of application, each opening serving as a stop.

Porous plasters are far more comfortable than the non-porous. With the laity the porous plaster seems to have wholly superseded the non-porous.

In dispensing plasters made with an India rubber base, the user should be instructed as to the methods of applying, which are, in brief, that the part to which the plaster is to be applied should be dry and clean. This, of course, can be accomplished by the ordinary method with soap and water, or with alcohol or other cleansing agents. Cleansing the skin is important, as it removes the skin coating and allows close contact with the plaster and quick absorption of the medicinal agent. Having applied the plaster, it should be rubbed until it conforms perfectly to the skin. The user should be instructed that if the cloth on the adhesive side of the plaster adheres too closely it can easily be removed by wetting it, in which case the plaster should be wiped dry before applying.

The removal of the rubber base plaster can be done easily and simply. The ordinary method is to lift one corner and pull the plaster off with a quick jerk. This is at times painful. A better method would be to wet a sponge or little piece of cotton with denatured or any other alcohol, raise one corner of the plaster, squeeze the sponge or cotton and allow the alcohol to trickle between the skin and the plaster. Under this process, the plaster will at once release its hold and practically drop off without further effort.

Chartæ—*Papers*

Papers are preparations intended principally for external application, made either by saturating paper with medicinal substances or by applying the latter to the surface of the paper by the addition of some adhesive liquid. One paper is official in the N. F. (see Charta Potassii Nitratis, page 523), but the most largely used paper is the *mustard paper*, commonly called a mustard plaster. These are prepared by the large manufacturers and must be wet with lukewarm water before applying.

CHAPTER CIX

SURGICAL DRESSINGS

Surgical dressings is a term applied to a wide range of materials used as coverings, protectives, or supports for diseased parts.

They are employed to rest and to hold in position parts liable to misplacement, to guard against accidental injury, to apply heat or medicaments to a diseased or injured part, to prevent wound infection, and to absorb and prevent decomposition of wound discharges.

Dressings may be classified as adhesive plasters, absorbents, paddings, compresses, poultices, protectives, bandages and splints.

Adhesive plasters are discussed elsewhere. (See page 1751.)

Absorbent Cotton—Cotton fiber is the base of most of the important and greatly varying forms of surgical dressings.

The natural fiber, mechanically cleaned of dirt, carded into layers, but not otherwise treated, known as "raw cotton" or "cotton wool", has a limited use for paddings and coverings of unbroken surfaces. This form is supplied under the name of *non-absorbent cotton.*

Absorbent cotton in its varied forms is the base of many surgical dressings, and is also used in the arts and for domestic purposes.

Absorbent cotton is prepared from the cotton fiber of the market, by a series of processes which remove all impurities and foreign substances and rendering the fibers absorbent. Briefly summarized, these processes include mechanical cleaning for the removal of leaves, stems, dirt, etc., and chemical treatment for the removal of the waxes, resins, fats, and coloring matter.

The chemical processes include boiling in alkaline solutions, treatment with chemical solutions, usually some form of chlorine, and the removal of the chemicals by successive baths in water. A practically pure and white cellulose fiber is the result of these processes. Cotton thus treated is then dried, passed through carding machines which lay the fibers, so far as possible, in parallel lines interlocked to form a thin film. The filmy layers, imposed one upon another, form the laps or folds of cotton which, when rolled with tissue paper, are the sheets of absorbent cotton as they appear on the market.

The cotton, after being treated as noted, is cut into folds of varying sizes and lengths and packed into cartons. In certain instances the packages are sterilized in vapors of formaldehyde and steam, and sealed.

Absorbent cotton is official in the U. S. P. under the title *Gossypii Purificatum* or *Purified Cotton* (see page 795).

Absorbent cotton forms the base of varied forms of pads, compresses, etc., for surgical and dental use. It is also formed into disks and squares for use in filtering milk, jellies, and other liquids.

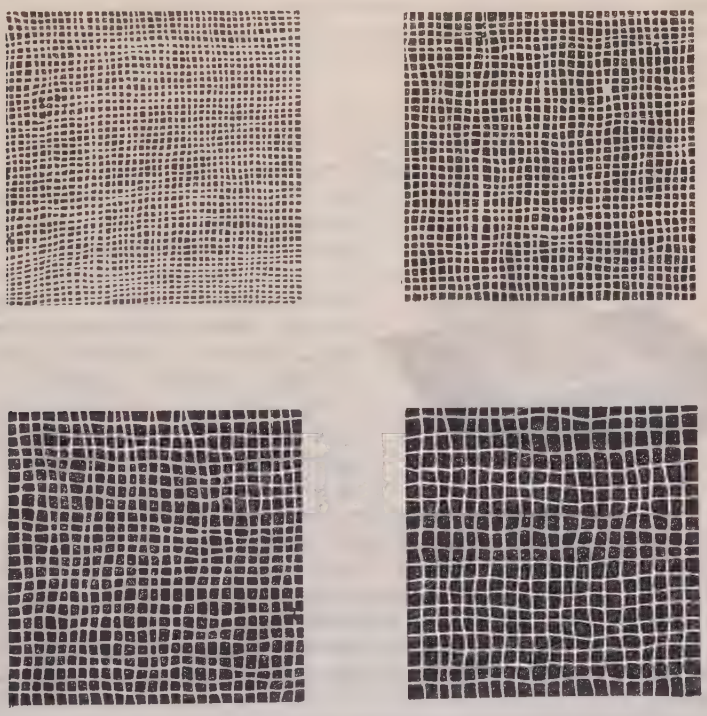
Each fiber of absorbent cotton is a hollow tube of highly absorbent cellulose which gives it peculiar powers as an absorbent and filtering material. The better grades of absorbent cotton are made from fibers approximately one inch in length, free from immature or unripe fibers which cannot be made absorbent.

Lower grades are manufactured from the combings and other wastes from cotton mills and, under such designations as "hospital grade", are used for coarser and mechanical purposes.

Absorbent cotton is also prepared by impregnating with antiseptics, forming the so-called medicated or antiseptic cottons. The principal varieties of antiseptic cotton are the following: *Borated cotton*, containing 10 per cent of boric acid; *iodoform cotton*, containing 5 per cent of iodoform; *iodized cotton*, impregnated with iodine; and *styptic cotton*, impregnated with a solution of ferric chloride. Cotton impregnated with other antiseptics, such as corrosive sublimate, phenol or carbolic acid, salicylic acid, etc., has a very limited use.

Surgical Gauze—Surgical gauze is a fabric of woven cotton fiber made absorbent, and differs materially from other cotton fabrics, such as muslin,

Fig. 755



Mesh of principal grades of gauze (actual size)

sheeting, cheesecloth, etc. In the process of making surgical gauze, the cotton fiber is mechanically cleaned and then spun or twisted into a thread, and the thread, in turn, woven into an open-mesh cloth.

The thread is loosely spun and the weave is open mesh in order that the resulting fabric may be soft, pliable and rendered absorbent.

Surgical gauze cloth is graded according to the number of threads or meshes per square inch, and the number of yards of fabric per pound. The mesh of the principal grades of gauze are shown in Fig. 755. For ascertaining the mesh or threads per inch, a small hand apparatus, known as a "pick" or "thread counter", is used (see Fig. 756).

The woven surgical gauze is rendered absorbent by processes quite similar to those employed in the preparation of absorbent cotton.

The gauze, after being made absorbent, is carried in a continuous length through a tentering machine, which stretches it to its full width, usually one yard, and then passes over a series of steam pipes and through rollers. When it leaves this apparatus, it is smooth and flat as though it had been ironed.

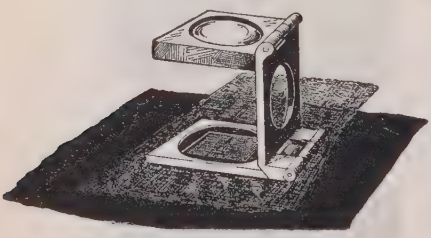
The gauze is cut into lengths, folded, rolled, and packed into various sized packages; it is also made into bandages and pads.

The final operation consists of sterilizing the packages before sealing.

Antiseptic or medicated surgical gauze came into vogue in the Listerian era of surgery, and it is still used to a considerable extent in various parts of the world. In the United States, however, plain medicated gauze is more largely employed. The antiseptic gauzes in common use are: *Borated gauze*, containing 10 per cent of boric acid; *corrosive sublimate gauze*, containing 1 to 1000 or 1 to 2000 corrosive sublimate; *carbolated gauze*, containing 5 per cent of phenol or carbolic acid; *iodoform gauze*, containing 5 per cent or 10 per cent of iodoform; *picric acid gauze* containing 2 per cent of picric acid. This last form is used as an application to burns.

Antiseptic gauze is prepared in both dry and moist form. The dry gauze is packed in sealed cardboard containers. The moist gauze is packed in glass jars, hermetically sealed. It is usually supplied in one and five yard lengths, and in narrow widths or strips for packing wounds. The gauze strips are made with a selvedge edge.

Fig. 756



Thread counter

Unless properly packed and cared for, antiseptic gauze is subject to change. Heat volatilizes carbolic acid and iodoform; iodoform is acted upon by light, especially sunlight.

Various forms of pads, compresses, and dressings are made from surgical gauze alone, or in conjunction with absorbent cotton.

Lint (*linteum*)—Lint was formerly a home-made product, consisting of a soft, fluffy fiber produced by scraping old linen cloth with the edge of a knife until a loose, tangled mass resulted. Modern lint is a specially woven cotton material in which loosely twisted threads form the warp of the material, while the cross threads are finer and more tightly twisted. The lint cloth is passed through a scraping machine which shreds the more loosely spun threads, producing a soft, fluffy surface of short fibers of cotton attached to a thread base.

Lint has great absorbent capacity and is used for absorbing discharges, and for the application of solutions, ointments, etc. Lint is supplied in the market in one-pound rolls and in smaller sized packets. In British and Continental practice, lint is supplied impregnated with antiseptics, chiefly boric acid.

Cellulose Wadding—This is sometimes called *wood wool*, and is wood pulp in the form of very thin sheets. It is very absorbent and, when several layers are put together or folded, it forms a substantial dressing. It has been used as a substitute for cotton. The disadvantages of cellulose wadding are its lack of elasticity, and the fact that when wet it becomes sodden.

Various pads and dressings are made from cellulose sheets, usually in conjunction with gauze as a binder.

Moss, *peat*, and *sawdust* have been used as materials for dressing wounds in emergencies, especially in the time of war when other dressings were not

available. These substances are harsh and are sterilized only with difficulty, and when used for wound dressing, must be enclosed in gauze or other fabric.

Jute is a fiber obtained from the inner bark of an herb of the linden family, also from the Indian mallow. It is a coarse, harsh fiber which, when treated and bleached, becomes somewhat absorbent and has a limited use for surgical dressings. Impregnated with a solution of tar it also has a limited field. Jute is usually packed in one-pound cartons.

Oakum or *marine lint* is manufactured from tarred rope, untwisted into a loose, fibrous mass. The tar has a slight antiseptic value. It is packed in cartons varying from one pound upward.

Bandages (*ligamentum*)—These terms usually imply strips or ribbons of muslin gauze, or other material employed in surgery for the retention of dressings, and for the compression, protection, or support of diseased or injured parts. They may be classed as inelastic, semi-elastic, and elastic. Still another class includes the bandages filled with hardening material, such as *plaster-of-Paris bandages*, which are virtually splints.

Ribbon, or *roller bandages*, are made of muslin, surgical gauze cloth, crinoline, etc., of widths from one-half inch upward, six or ten yards in length, and are usually rolled into firm even cylinders. *Muslin* (*calico*) roller bandages are made of bleached or unbleached muslin; the unbleached being the more commonly employed because of their softness.

Gauze bandages (*carbasus*) are made of the finer, firmer grades of surgical gauze, usually with edges ravelled; each bandage is wrapped and sealed.

A form of bandage known in England, as *water dressing bandages*, is made of a special grade of bleached cloth, heavier and more closely woven than gauze, but not as firm as muslin. They are absorbent and firm and are used largely for the application of solutions.

Crinoline bandages are gauze bandages stiffened with dextrin. They are usually wet before applying, and upon drying form a firm support. They also form the base upon which the plaster-of-Paris is applied.

Starch bandages are gauze bandages impregnated with starch paste. Their use is similar to that of the crinoline bandage.

Triangular bandages are usually made by cutting a square of cloth diagonally from corner to corner, forming two right triangles of equal size and shape. These bandages were brought into prominence by Esmarch and carry his name. They are particularly adapted for emergency use and can, with safety, be applied by inexperienced hands. Bandages, slings, and compresses, can readily be constructed from triangular bandages. The *triangular bandage* is particularly adapted for military, police, and railway service. This bandage usually comes printed with illustrations showing methods of application and is made a component part of First Aid packages.

Elastic bandages are bandages made to secure elastic compression or constriction of limbs, etc. Those made of India rubber are made of the pure gum vulcanized, or of threads of rubber woven with silk or other threads into a webbing.

Crêpe bandages are elastic, but contain no rubber. They are constructed of wool, or cotton and wool combined. The peculiar weave employed gives elasticity.

Flannel bandages are semi-elastic. They permit a certain amount of swelling in the part to which they are applied without producing undue pressure. They also retain the body heat. They should be made of pure wool which has been shrunken.

Plaster-of-Paris bandages are composed of gauze ribbons (crinoline is

sometimes employed), through the meshes of which the powdered plaster is distributed. The bandage when wet becomes plastic and upon drying or "setting" a cast or splint is formed. The plaster-of-Paris used to form the bandage should be a grade suitable for surgical uses, of a moderate setting time, *i.e.*, neither too fast nor too slow. The addition of common salt to the water with which the bandage is wetted will accelerate the speed of the setting of the plaster. One heaping teaspoonful of salt to a gallon of water speeds the setting time about one-third. Gelatin and glue will retard or destroy the setting properties.

Difference of manipulation used by operators is, at times, the cause of complaint in respect to these bandages. The following is the procedure employed by successful operators.

A vessel deep enough to hold one bandage standing on end should be nearly filled with water and placed on a table. Water of ordinary temperature is satisfactory.

The bandage should be completely submerged, and squeezed several times with the fingers to work out the air and allow the water to enter. It should be allowed to remain in the water not more than one minute, then removed, the excess water squeezed out, and applied as rapidly as possible. If, during application, there are parts where the plaster seems too dry water may be added from time to time by sprinkling on with the fingers. If there are parts of the gauze not properly covered with plaster (and this is likely to occur with the first few turns owing to having been washed out by the water), more should be sprinkled on from an excess supply, provided for the purpose. By smoothing and stroking with the hand as the application progresses, a solid, strong cast of good appearance can be produced.

Plaster-of-Paris bandages are supplied by the manufacturers in lengths of five yards and of varying widths. Each bandage is wrapped in paper with an excess of plaster packed in a sealed container. Plaster-of-Paris bandages must be kept in sealed, air-tight and moisture-proof containers, and stored where they will remain perfectly dry. The entrance of moisture into the container will cause a reaction in the plaster and its efficiency will be impaired.

Stockinette bandages are made of stockinette material knitted or woven in tubular form, without seams. They are usually supplied three inches wide, flat measure, five yards in length. They are used to cover the skin prior to the application of a plaster-of-Paris bandage.

Protectives—These are employed as wound coverings, either to shield the parts from external infection, or to prevent the escape of fluids contained in the dressing, and are also used as a covering for poultices, and for the retention of heat. In common use as protectives are oiled silk, oiled muslin, gutta percha tissue, rubber, wax or paraffined paper, and mackintosh or jaconet.

Oiled silk (*sericum oleatum*) is a thin, fine silk, coated with a flexible linseed oil varnish. Two varieties are made, one is semi-transparent, the other variety is opaque, made so by the application of talc or starch with the final coating. It is a very soft, pliable fabric, and is supplied in packages of one and five yard lengths, and also in smaller squares.

Oiled muslin or *oiled cambric* (*sindon oleata*) is similar to oiled silk, except that the basic fabric is of glazed cotton. It is thicker and heavier, and consequently less pliable than oiled silk.

Oiled silk and oiled muslin are liable to deteriorate with age, owing to the decomposition of the coating when subject to moist, humid atmosphere. They should be kept dry with access of air to the interior of the containers.

Waxed or paraffined paper is prepared by passing a parchment-like sheet of

paper through melted wax or paraffin. It is used largely as an economical substitute for more expensive protectives.

Gutta percha tissue consists of a thin, tissue-like sheet of gutta percha. While it is soft and pliable, it is lacking in strength and is quite liable to deteriorate with age. It is destroyed by hot solutions.

Rubber dam is a fine, thin tissue of pure India rubber, soft, pliable and elastic. It can be cleansed with soap and hot water, steam, or boiling water, and is employed for purposes similar to oiled silk or oiled muslin. It is liable to deterioration with age.

Mackintosh or *jaconet* is a thin, firm cotton cloth, coated upon one side with a layer of India rubber. It is a soft, pliable fabric and is often used as a covering for moist dressings, poultices, etc.

Rubber sheeting is a rubber-coated cloth, waterproof and flexible. It is supplied in various lengths and widths for use as a covering for bedding. One form used as a protection blanket is provided with eyelets for lacing under the bed. A so-called "nursery sheeting" is supplied, coated only on one side.

Care of Surgical Dressings

Surgical dressings of every nature must be properly cared for in order that their integrity may be preserved. The most suitable storage places are dustproof cases of glass or wood. The storage place should be dry and not near steam or furnace heat.

The absorbency and the whiteness of absorbent cotton and gauze are affected by prolonged contact with heat.

Many of the antiseptics contained in surgical dressings are volatilized by heat.

Some forms of surgical dressings are affected by the rays of the sun which act upon many of the antiseptics contained in these products.

Surgical dressings must be kept clean, free from dust, and handled carefully and with clean hands. Packages containing surgical dressings should be delivered to the consumer in sealed packages. The packages should not be opened and the contents exposed except at the time of use. Exposure of surgical dressings to dust, and especially to unnecessary handling is liable to be a means of conveying infection. The practice of selling small portions of dressings from large containers is especially objectionable.

ANTISEPTIC DRESSINGS IN THE BRITISH PHARMACEUTICAL CODEX (1924)

Carbasus Acidi Borici, B. P. C., Boric Acid Gauze, Boric Gauze.
Boric acid, distilled water (boiling), aniline red, unmedicated gauze, of each, a sufficient quantity.
Prepared by immersing the gauze in a saturated solution of boric acid in the boiling distilled water, tinted with aniline red, pressing the gauze, and drying. Contains from 10 to 15 per cent of boric acid.

Carbasus Acidi Carbolici, B. P. C., Carbolic Acid Gauze, Carbolic Gauze, Phenolated Gauze.
Phenol, 2 ounces, resin, 8 ounces, hard paraffin, 8 ounces, unmedicated gauze 18 ounces.
Prepared by melting together the phenol, resin, and paraffin, saturating the gauze with the mixture, and pressing between warm metal plates. Contains from 5 to 6 per cent of phenol.

Carbasus Acidi Picrici, B. P. C., Picric Acid Gauze, Picric Gauze.
Picric Acid, 146 grains, distilled water (warm), 35 fl. ounces, unmedicated gauze, 16 ounces.
Prepared by dissolving the picric acid in the warm distilled water, saturating the gauze with the solution, and drying. Contains from 1.5 to 2 per cent of picric acid.

Carbasus Aluminii Acetatis, B. P. C., Aluminium Acetate Gauze.
Solution of Aluminium Acetate, 8 fl. ounces, distilled water, 8 fl. ounces, absorbent gauze, 16 ounces.
Prepared by saturating the absorbent gauze with the mixture. Strength approximately 3 per cent.

Carbasus Hydrargyri Perchloridi, B. P. C., Mercuric Chloride Gauze, Sublimate Gauze.
Solution of mercuric chloride (1 in 1000), 16 fl. ounces, unmedicated gauze, 16 ounces.
Prepared by soaking the gauze in the solution of mercuric chloride so that the solution is equally distributed, and drying. Contains from 0.1 to 0.15 per cent of mercuric chloride.

Carbasus Hydrargyri et Zinci Cyanidi, B. P. C., Mercury and Zinc Cyanide Gauze, Double Cyanide Gauze.

Double cyanide of mercury and zinc, ½ ounce, solution of mercuric chloride (1 in 4000), 35 fl. ounces, aniline violet, a sufficient quantity, unmedicated gauze, 16 ounces.

Prepared by diffusing the cyanide of mercury and zinc in the solution of perchloride of mercury, colored lightly with aniline violet. Place the gauze in the mixture, pressing and agitating, so that the insoluble powder is equally diffused over the gauze.

Contains, when dry, from 2 to 3 per cent of mercury and zinc cyanide.

Carbasus Iodoformi, B. P. C., Iodoform Gauze.

Iodoform, ½ ounce, ether, 8 fl. ounces, unmedicated gauze, 9½ ounces.

Prepared by dissolving the iodoform in the ether, and pouring the solution on the gauze under pressure; when the whole of the liquid is absorbed and equally diffused, allowing the ether to evaporate. Contains from 4 to 5 per cent of iodoform.

Carbasus Iodoformi cum Glycerino, B. P. C., Iodoform Gauze with Glycerin, Moist Iodoform Gauze.

Iodoform, 2 ounces, glycerin, 2 fl. ounces, ether, 16 fl. ounces, unmedicated gauze, 16 ounces.

Dissolve the iodoform in the ether, add the glycerin, and pour the mixture on the gauze under pressure. Allow the ether to evaporate in a current of air.

Carbasus Salis Alembroth, B. P. C., Sal Alembroth Gauze, Blue Gauze.

Alembroth salt, 70 grains, distilled water, 16 fl. ounces, aniline blue, a sufficient quantity, unmedicated gauze, 16 ounces.

Prepared by dissolving the alembroth salt in the water, and tinting with the dye, placing the gauze in the solution, pressing until the gauze has absorbed all the solution. Contains from 0.75 to 1 per cent of alembroth salt.

Carbasus Styptica, B. P. C., Styptic Gauze, Tarred Gauze.

Tar, 380 grains, resin, 230 grains, benzene, 14 fl. ounces, absorbent gauze, 16 ounces.

Dissolve the tar and resin in the benzene, allow to stand for twenty-four hours, and saturate the gauze with it. Dry the gauze in a steam-heated chamber where there is a good current of air. Strength approximately 5 per cent.

Carbasus Zinci Sulphitis, B. P. C., Zinc Sulphite Gauze.

Zinc sulphate, 1 oz. 17½ gr., sodium sulphite, 385 grains, distilled water, 32 fl. ounces, gentian violet, a sufficient quantity, absorbent gauze, 16 ounces.

Dissolve the salts separately in warm distilled water, mix and add sufficient water to produce 100 (16 fluidounces). Slightly color the solution with gentian violet, immerse the absorbent gauze in the colored liquid, and press it so that the whole of the mixture is evenly absorbed. Now submit the gauze to strong pressure to remove the sodium sulphate formed, immerse in distilled water, 100 (16 fluidounces), and again press to remove sodium sulphate, then dry.

Strength approximately 5 per cent.

Gossypium Acidi Borici, B. P. C., Boric Acid Wool, Boracic Acid Wool; Boric Wool.

Boric acid, 16 ounces, absorbent cotton, in thin sheets, 16 ounces, distilled water, boiling, a sufficient quantity.

Prepared by making a hot saturated aqueous solution of the boric acid tinted with aniline red, immersing the cotton in the liquid, removing the sheets to wire trays, and allowing to drain and cool. The medicated cotton is afterwards pressed sufficiently and dried. Contains from 15 to 25 per cent of boric acid.

Gossypium Acidi Salicylici, B. P. C., Salicylic Acid Wool, Salicylic Wool.

Salicylic acid, 292 grains, alcohol, 16½ fl. ounces, absorbent cotton, 16 ounces.

Dissolve the salicylic acid in the alcohol, and pour the solution over the cotton under pressure. Then dry in thin layers. Contains 4 per cent of salicylic acid.

Gossypium Acidi Salicylici Forte, B. P. C., Strong Salicylic Acid Wool.

Salicylic acid, 1 oz. 340 grains, alcohol, 16½ fl. ounces, absorbent cotton, 16 ounces.

Same process as the foregoing. Contains 10 per cent of salicylic acid.

Gossypium Capsici, B. P. C., Capsicum Wool.

Liquid extract of Capsicum, 2 fl. ounces, absorbent cotton, in thin sheets, 18 ounces, alcohol, 14 fl. ounces.

Mix the extract with the alcohol, and pour the solution over the cotton, under pressure.

Gossypium Carbolisatum, B. P. C., Carbolised Wool.

Phenol, in crystals, 368 grains, ether, 16¾ fl. ounces, absorbent cotton, 16 ounces.

Dissolve the phenol in the ether, and pour the solution over the cotton under pressure. Approximately of 5 per cent strength when freshly made.

Gossypium Ferri Perchloridi, B. P. C., Ferric Chloride Wool, Perchloride of Iron Wool; Gossypium Stypticum; Styptic Wool.

Ferric chloride, 2 oz. 360 grains, distilled water, 19 fl. ounces, absorbent cotton, 16 ounces.

Dissolve the ferric chloride in the water, saturate the cotton evenly with the solution, dry by exposure to the air.

Gossypium Hamamelidis, B. P. C., Hamamelis Wool.

Tincture of hamamelis, 50 fl. ounces, glycerin, 3 fl. ounces, absorbent cotton, 15 ounces.

Mix the glycerin with the tincture, saturate the cotton evenly with the mixture, dry by exposure to the air.

Gossypium Hydrargyri et Zinci Cyanidi, B. P. C., Mercury and Zinc Cyanide Wool, Double Cyanide Wool.

Mercury and zinc cyanide, 216 grains, solution of mercuric chloride (1 in 4000), 32½ fl. ounces, absorbent cotton, 16 ounces, aniline violet, a sufficient quantity.

Diffuse the mercury and zinc cyanide in the solution of mercuric chloride, and color lightly with the aniline violet. Place the absorbent cotton in the mixture. When the whole of the mixture is absorbed dry the "wool."

Gossypium Hydrargyri Iodidi, B. P. C., Mercuric Iodide Wool; Biniodide of Mercury Wool; Red Iodide of Mercury Wool.

Mercuric Iodide, 7 grains, potassium iodide, 7 grains, distilled water, 16 fl. ounces, absorbent cotton, 16 ounces.

Dissolve the salts in the water, diffuse the solution evenly through the cotton under pressure, and dry. Strength 1 in 1000, sometimes colored pale red by adding a little eosin to the medicated solution.

Gossypium Hydrargyri Perchloridi, B. P. C., Mercuric Chloride Wool, Perchloride of Mercury Wool, Sublimate Wool.

Mercuric Chloride, 35 grains, glycerin, 35 minims, distilled water, 32 fl. ounces, absorbent cotton, 16 ounces.

Dissolve the mercuric chloride in the glycerin and water, immerse the cotton in the solution, and press out the liquid until the medicated cotton weighs 32 ounces, and dry.

Gossypium Iodisatum, B. P. C., Iodised Wool, Iodine Wool.

Iodine, 1 ounce, potassium iodide, 1 ounce, glycerin, 2 fl. ounces, ether, 20 fl. ounces, absorbent cotton, 16 ounces.

Dissolve the iodine and potassium iodide in the ether, add the glycerin, saturate the cotton evenly under pressure. Then dry.

Gossypium Iodoformi, B. P. C., Iodoform Wool.

Iodoform, 1 oz. 340 grains, ether, 16 fl. ounces, absorbent cotton, 16 ounces.

Dissolve the iodoform in the ether, and pour the solution over the cotton under pressure. Allow the ether to evaporate. Approximately of 10 per cent strength.

Gossypium Menthol, Menthol Wool.

Menthol, 1 oz. 340 grains, liquid paraffin, 1 fl. ounce, ether, 50 fl. ounces, absorbent cotton, 16 ounces.

Dissolve the menthol in the ether, add the liquid paraffin, shake thoroughly, and saturate the cotton evenly with the mixture. Dry by exposure to the air.

Gossypium Menthol Compositum, B. P. C., Compound Menthol Wool.

Menthol, 306 grains, solution of formaldehyde, 288 minims, oil of lavender, 288 minims, oil of eucalyptus, 288 minims, alcohol, 20 fl. ounces, absorbent cotton, compressed, a sufficient quantity.

Dissolve the menthol in the alcohol, add the oils and solution of formaldehyde. Soak sheets of the compressed absorbent cotton in the mixture, and dry.

Gossypium Salis Alembroth, B. P. C., Sal Alembroth Wool, Blue Wool.

Alembroth salt, 286 grains, distilled water, 32½ fl. ounces, aniline blue a sufficient quantity, absorbent cotton, 16 ounces.

Prepared by dissolving the salt and aniline blue in the water, immersing the cotton in this solution, removing, pressing sufficiently and drying. Contains from 0.75 to 1 per cent of alembroth salt.

CHAPTER CX

FIRST AID DRESSINGS

FORMERLY, in the case of an accident on the street or elsewhere, the victim was carried to a drug store, and the pharmacist was called upon to apply "first aid" treatment.

Modern first aid requires its application by more or less trained workers in the factory, work shop, store, household, or wherever the accident may occur.

Under this system, the pharmacy becomes a depot from which the necessary supplies for the administration of first aid may be secured.

The prime office of first aid is to relieve the injured person from immediate suffering and prevent further injury, this aid to be applied at the place where the injury occurred. After first aid is applied, the next step is to remove the person to a place where medical and surgical attention may be rendered.

It may be borne in mind, that permanent treatment, care of injuries, administration of medicines, diagnoses, and treatment of disease or injuries, have no part in first aid.

In modern times, large numbers of lay people, through the associated efforts of the Red Cross Society and first aid organizations, have been trained to give first aid service successfully.

It is the province of the pharmacist to direct his patrons in the selection of first aid appliances, and, so far as possible, as to the proper method of applying the same.

In a large number of the states, equipment of factories, work shops, etc., with "First Aid Outfits" is required by law. An example of this is found in the Industrial Code of the Department of Labor of the State of New York, which requires that in every factory employing more than ten persons, in which power machinery is used, there shall be provided a First Aid Cabinet accessible at all times. The content of the First Aid Cabinet under these regulations is as follows:

Instruments

1 pair scissors,
Thumb forceps,
Tourniquet,
Graduated medicine glass.

Drugs

2 oz. aromatic spirit of ammonia,
2 oz. 4 per cent boric acid solution,
2 oz. alcoholic iodine solution, half strength (for external use),
2 (3 oz.) collapsible tubes of bicarbonate of soda mixed with petrolatum (3 per cent) (for burns),
2 oz. castor oil (for eye injuries)

Dressings

1 doz. assorted sizes, sterile gauze bandages,
1 spool ZO adhesive plaster, 1 inch by 5 yards,
3 (½ oz.) packages of absorbent cotton,
3 (1 yard) packages of sterile gauze,
Splints of assorted sizes for fractures,
Wooden applicators wound with cotton,
Wooden tongue depressors.

The Liability Insurance Acts of many states, likewise require the installation of a *First Aid Kit* or *Outfit* containing the following articles:

Instruments

1 pair scissors,
3 pairs splinter forceps,
Tourniquet,
Graduated medicine glass (unless medicine is furnished in ampuls).

Drugs

2 oz. (or a minimum of 10 ampuls) aromatic spirits of ammonia,
Boric acid, liquid, powder or tablet form to make 4 per cent solution,
2 oz. (or a minimum of 10 ampuls) iodine solution, half strength (for external use),
2 collapsible tubes (3 oz. each, or at least 6 individual tubes of burn dressing),
2 oz. castor oil (for eye injuries).

Dressings

1 doz. assorted sizes, sterile gauze bandages, or
1 doz. assorted compresses in sealed packets,
1 spool adhesive plaster, 1 inch by 5 yards,
3 packages (½ oz. each) of absorbent cotton,
Splints of assorted sizes for fractures, or wire splints,
Wooden applicators wound with cotton.

Manufacturers of dressings supply cases of this character in compact form for factory use.

First aid is rapidly being extended beyond its original inception to all walks of life. This is particularly true in respect to the greatly increased use of automobiles, and the liability to accidents in the home, on the farm, and in other places. Outfits are now supplied for these special uses, even to small pocket outfits.

Pharmacists are often called upon to supply not only the first aid material for use in the home, but for simple domestic remedies for emergency use in case of sudden illness.

First aid is likewise being extended to measures for the prevention of the spread of contagious and infectious disease. For all of these phases of first aid, the trained pharmacist should be well fitted.

It is recommended that every pharmacist become familiar through the use of first aid manuals, and otherwise, with emergency measures that may, so far as possible, tend to educate his patrons in first aid, and induce them to install in their households or shops, equipment of this character.

CHAPTER CXI

LIGATURES AND SUTURES

This important class of surgical materials is largely prepared by special manufacturers, the pharmacist, however, must handle and dispense the prepared material, hence the necessity for an intimate acquaintance with the various kinds of these articles. An explanation of the more common terms is here given in a condensed form.

The terms "ligature" and "suture" are often used as of equivalent meaning. The difference between the two is quite distinct.

Ligature, when used as a noun, means the thread or cord with which an artery or vein is tied to prevent or arrest hemorrhage. It is also applied to a cord, thread, or wire used to remove tumors, etc. When used as a verb, it means to tie.

Suture, when used as a verb, means to stitch or to sew. In surgery it means the stitching together of the edges or lips of a wound to assist nature until normal union is effected. Suture material is used in sewing together tissues, blood vessels, nerves, bones, etc., until normal union is performed by nature. The same material, however, is used both for sutures and ligatures.

Material used for ligatures and sutures may be divided into two general classes, *viz.*, the "absorbable" and the "non-absorbable".

Absorbable Sutures—This type of sutures or ligatures are those which, during the healing process, are absorbed by the tissues in which they are imbedded. The absorbable materials most commonly used are catgut and animal tendon. Animal tendons consist of layers of longitudinal fibers which are split to form a suture of suitable size. Animal tendons are readily absorbed.

The tendon of the kangaroo (wallaby) is the best known and the most used of all animal tendons. For use as sutures or ligatures the tail tendons are split into rather irregular sizes. Kangaroo tendons cannot be accurately gauged as to size and length. They are roughly divided into fine, medium, and coarse, as to size, with an average length of twelve inches. Kangaroo tendon suffers deterioration by steam sterilization, boiling in water, and by heat processes generally.

Surgical catgut is descended from the musical string. The term "catgut" is generally explained upon the basis that the word itself was originally derived from "kitgut" or "kitstring", meaning a fiddle, and this term has become confused with "kit", meaning a little cat. Modern catgut is really sheep gut. Catgut as made from sheep intestine, is a ribbon-like material twisted into a cord, presenting the most acceptable type of absorbable suture.

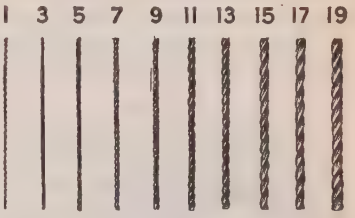
Absorbable suture material can be treated so as to resist absorption, *e.g.*, *hardened, chromic*, or *tanned catgut.*

Non-Absorbable Sutures—Certain suture materials are in use which are practically non-absorbable and, as such, remain in the tissues for an indefinite length of time. Examples of such substances are silk, silkworm gut, linen, horsehair, and the various metallic wires, such as silver, copper, aluminum, bronze, etc. It may be noted that in the course of time, sometimes years, these so-called "non-absorbable" sutures disintegrate and disappear, but they are not absorbed during the process of wound healing. This, however, does not happen in the case of hardened catgut, which disappears within varying periods.

Silk Sutures—The silk fiber consists of a continuous thread spun by that species of caterpillar known as the silkworm. The so-called mulberry silkworm, cultivated in many countries, produces the bulk of the silk of the market. The silk fiber is obtained by unreeling the cocoon, and this produces what is known as raw silk. The short tangled fibers from the exterior of the cocoon are the source of floss silk from which, in turn, spun silk is made.

The chief chemical constituents of silk consist of sericin, fibroin, resins, fats, and mineral matter. Fibroin is a proteid analogous to that contained in wool. Sericin, an altered form of fibroin, is the so-called silk glue which forms the outer coating of the fiber. Silk is notable for its tensile strength, which is stated to be equal to that of an iron wire of equivalent diameter. It is very elastic.

Fig. 757



Twisted Silk (Sizes 1 to 20)

Silk will withstand a temperature of 110° C. without decomposition. It is dissolved by strong, hot alkalies, and by concentrated sulphuric or hydrochloric acid. Silk readily absorbs coloring matter and dyes.

The threads, as spun by the silkworm, are twisted and braided together to form what are known technically as *"twisted silk"* and *"braided silk"*, respectively. Raw silk is cream or orange color. As found in the market, however, it is white, due to scouring and bleaching.

Many surgeons prefer silk sutures that have been dyed black, this color being more readily perceptible in the wound tissues. Silk of this type is known as *"iron dyed"*. The exact sizes are shown in Fig. 757.

Silkworm Gut—Silkworm gut is made direct from the silkworm before it forms its cocoon.

Silkworm gut is a cream white, smooth, lustrous material, but it is quite stiff, and is usually soaked in warm or hot water before attempting to tie it. The diameter of silkworm gut is irregular and limited. In surgery, silkworm gut is used principally for suturing the skin.

A recent innovation is a so-called *"artificial silkworm gut"* which is said to be made by taking a strand of twisted silk and coating it with a solution of silk. This form of suture is very pliable, but is not as strong as the natural product. It can be produced in long strands and many sizes. It is used primarily as a skin suture.

Linen Sutures—These are literally linen thread, and ordinarily, are used in their original grayish-white form. Some operators, however, prefer the black linen cord.

A form known as "Pagenstecher's Linen" is a linen thread impregnated with celluloid. This is to overcome capillarity and thus prevent infection from being carried into the wound by the strand. The coating increases the tensile strength and overcomes any tendency to irritate. This form is but little used.

Linen thread, coated with paraffin or with beeswax, has some use.

Horsehair Sutures—These sutures are taken from the tail of the horse and are prepared for surgical use as follows: They are first subjected to a thorough cleansing, with boiling water and soap, to remove the gross dirt. This is followed by repeated washing and sterilizing in hot water and steam. Owing to the liability of the presence of tetanus and other organisms in horsehair, a thorough sterilization is required.

Horsehair is a fine, elastic substance with very little tensile strength. It is

used chiefly for the suturing of the skin, particularly about the face, neck, and lips, and leaves but little scar or cicatrix.

No particular gradation of sizes for horsehair sutures can be made. They are usually supplied in approximately uniform lengths, packed in tubes or envelopes, and sterilized within the container.

Wire Sutures—Silver wire sutures are made of drawn wire of silver alloyed with copper. As it cannot be knotted, it is fastened by twisting the ends. In surgery, the main use for silver wire is for suturing the bones. Wire sutures have been made of other metals, such as aluminum, bronze, etc. At present, however, they are but little used. Metallic sutures in the course of time disintegrate and disappear in the tissues.

Catgut—Catgut is the product of the intestines of the sheep. The intestines are tubes from sixty to seventy feet long. For surgical purposes only about one-third of the tube can be utilized.

The intestinal tube has been compared to a garden hose consisting of layers of tissue with elastic properties in several directions. It is made up of four distinct coats or layers, a central mucous layer, a so-called submucous layer, and two muscular layers, one with lengthwise fibers and the other in which the fibers run crosswise (see Fig. 758). In the process of manufacture, all the layers except the submucous are removed.

FIG. 758

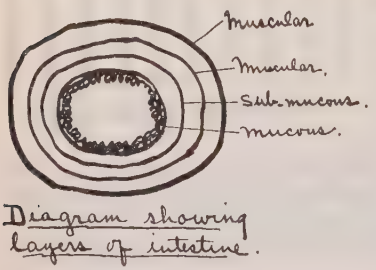


Diagram showing layers of intestine.

The process of preparing the intestines includes the removal of the fecal contents, the splitting of the tube into halves, the separation of the tissue layers, which is done under systems of cleansing, washing and disinfection. The separate ribbons are then twisted into a cord, dried and polished, gauged, and wound into coils for the subsequent sterilization processes.

Catgut, from a chemical point of view, is a complex albuminoid substance, an organized collagen. In terms of physiological chemistry, "a colloidal substance known is collagen, or the parent substance of glue and gelatin".

Approximately, catgut contains over seventy per cent of collagen convertible into gelatin, ten per cent of proteins not convertible into gelatin, two per cent of carbohydrates, waxes, fats, etc., and about three per cent of inorganic constituents, ash, etc.

The complex composition of catgut indicates the action liable to follow in the course of its manipulation and preparation for surgical use. Acids, alkalies, and most chemical substances act upon the collagen in a greater or less degree. Tannin, formaldehyde, alum, mercuric chloride, and other like substances react upon collagen. Watery fluids, especially under the influence of heat are highly destructive to catgut tissue. Many antiseptic agents react upon catgut, but not always destructively. Heat can be applied to catgut in the process of sterilization, provided the catgut is perfectly free from moisture.

It is apparent that a complex substance, such as catgut, when imbedded in a wound, after performing its office of holding the wound tissue together, must undergo a series of changes before being absorbed in the healing process.

Hardened Catgut—Catgut and other absorbable suture material can be so treated that the processes of absorption will be retarded. The process in quite general use consists of treating the gut with a solution of chromic acid or a salt of chromic acid. The strength of the chromicizing bath and the period of exposure govern the degrees of hardness or resistance to absorption that may be desired.

The chromicizing process originally devised by Lister, and still used with modifications by manufacturers, is as follows: Soak the catgut during twenty-four hours in 20 times its weight of "preparing liquid", made as follows: Dissolve chromium trioxide in 240 parts of water, by weight, add sufficient sulphurous acid to produce the green color of chromium sulphate ($Cr_2(SO_4)_3$). Then add sufficient water to make 480 parts by weight. Next add a solution consisting of 2 parts of mercuric chloride in 320 parts of water, by weight. Dry the catgut on the stretch. (*British Medical Journal*, 1908, Vol. I, 125.)

The terms "ten", "twenty", and "thirty", day have been applied as indicative of the time in which the strand would resist absorption. These terms cannot be construed literally. The time of absorption varies with the individual patient and the tissue in which the strand may be imbedded. Quite generally catgut is supplied in two grades of hardness, using the terms "*medium-hard chromic*" and "*extra-hard chromic*". These are purely relative terms, used to indicate the degree or rate of resistance that the catgut offers against absorption when imbedded in the tissues.

As indicating the relative value of these terms it may be stated that under ordinary conditions in the striated muscle, the material known as "medium-hard" chromic catgut, size No. 2, will retain its integrity for from ten to twenty days, whereas the "extra-hard" chromic catgut will retain its integrity for from thirty to forty days, or perhaps longer.

Methods of Preparing Catgut

The methods which have been devised for the preparation of catgut for surgery number several hundred. They have been subject to constant modification and change, hence have not become standard. Methods in use for preparing various forms of Antiseptic Catgut will be found in the *A. J. P.*, Vol. 95, p. 737.

Modern Methods—Manufacturing laboratories have adopted methods for the preparation and sterilization of ligatures which are designed to fulfil present day surgical requirements. Different treatment is necessary for the different varieties of ligature material; no general process can cover them all. Certain prominent features are present in all processes, the chief characteristic in most cases being the thermol treatment. In some instances, the processes are carried out upon the twisted strand of catgut, in other cases the processes begin with the cleansing and disinfection before the tissue is twisted to form the cord. Practically, such a method involves a continuous series of processes, carried out along the following lines.

1. The cleansing and disinfection of the intestines directly after their removal from the sheep.
2. Disinfection of the individual ribbon.
3. Twisting the ribbon under sanitary conditions (see Fig. 759).
4. Dehydration and extraction of fats and waxes, etc.
5. Heat sterilization applied in kind, quantity and manner to assure the effective destruction of all organisms that may be present. This is ordinarily performed by boiling in cumol or an equivalent hydrocarbon at a temperature reaching or exceeding 152° C.
6. Storing in tubes or envelopes and sealing.
7. Sterilizing after the tubes or envelopes are sealed.
8. Bacteriological examination of each lot for verification and control of sterility.

The aim of such methods is to destroy and eliminate organisms present in the gut tissue so as to avoid contamination in the process of manufacture and protection in subsequent handling. In certain instances, antiseptics are added during the process or in the storing fluid.

The modern method combines a thorough continued disinfection or sterilization, not dependent upon any one feature, or upon the power of any antiseptic, or any one degree of heat, but upon the combination of the whole.

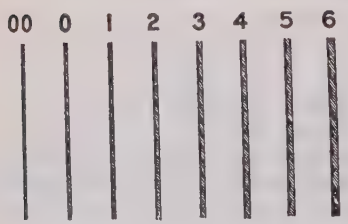
Catgut Sizes—Formerly catgut sizes were designated by the letters used in the musical string trade, A, B, C, etc. This system was changed to the use of

Fig. 759

Preparing catgut

numbers. The Brown and Sharpe wire gauge is sometimes used in the measurement of the strands. Latterly a rational scale of measurement has come into use for catgut. This scale is based upon the thousandths of an inch, each size being three-thousandths of an inch increase over the next smaller one. While some slight variation in size cannot be avoided, this system gives a more

Fig. 760



Catgut Size Scale (exact size)

Catgut Size Scale

No.	Thousandths Inch	No.	Thousandths Inch
00	12	4	27
0	15	5	30
1	18	6	33
2	21	7	36
3	24		

regular sized strand. The exact sizes for catgut are exhibited in the table here shown, Fig. 760.

Sizes of Silk Ligatures—The standard for silk ligatures is based upon the yardage per ounce. The following table shows the approximate yardage per ounce of the twenty sizes used in surgery.

Surgeons' Twisted Silk

No.	Yards to Ounce	No.	Yards to Ounce
1	2265	11	299
2	1865	12	232
3	1532	13	170
4	1198	14	136
5	932	15	115
6	765	16	95
7	565	17	80
8	465	18	65
9	444	19	50
10	365	20	40

Surgeons' Braided Silk

No.	Yards to Ounce	No.	Yards to Ounce
1	670	11	90
2	414	12	80
3	356	13	63
4	320	14	50
5	223	15	45
6	177	16	41
7	170	17	36
8	148	18	31
9	120	19	28
10	103	20	24

Surgeons' white as well as the so-called "iron-dyed" or black silk are of the same sizes.

Surgeons frequently use the designations "*fine*", "*medium*" and "*coarse*", which, respectively, would be equivalent to numbers 5, 9, and 12, in twisted silk, and 4, 7 and 10, in braided silk. Approximately, numbers 5, 9, and 12, in twisted silk, and 4, 7, and 10, in braided silk, are equivalent to numbers 1, 2 and 3, in catgut.

Silk is stronger than catgut of the same size, and is not weakened by the ordinary processes of sterilization, or by a variety of influences which tend to weaken catgut and other sutures.

Tensile Strength of Catgut

The tensile strength of ligature material is usually sufficient for the purpose to which it is applied, and, with the exception of catgut, is seldom brought into question. The peculiar nature of catgut tissue, the methods employed in sterilization and manipulation affect its tensile strength. Any attempt to judge the tensile strength of a strand of catgut by pulling or jerking the strand will be deceptive. A sudden jerk will break a heavy cord or even a piece of wire. In absence of proper apparatus, a strand may be held firmly between the hands and given an even, steady pull until the breaking point is reached.

Manufacturers use an apparatus made primarily for testing the strength of yarns similar to the machine illustrated in Fig. 743. In absence of such an apparatus, a hand spring scale (see Fig. 761) gives approximate results. Caution should be observed in testing a strand that it is free from kinks, nicks, splinters, or weakened points, as the cord is most liable to break at such spots. A catgut cord not uniform from end to end may break at a certain place, and yet be strong at all other points. The following table gives the average approximate breaking point of catgut on a straight pull, as shown by a yarn testing apparatus.

Approximate Breaking Point of Surgical Catgut

Size	Pounds	Size	Pounds
00	4	4	21
0	6	5	24
1	8	6	27
2	12	7	30
3	18		

The Selection of Ligature and Suture

It is the province of the surgeon to select the kind and size of material which he may desire to use in a given condition. The pharmacist, however, should be sufficiently informed to discuss the subject intelligently, if called upon to assist the surgeon in his selection.

The office of a ligature or suture in a wound is to hold the parts together until the healing process takes place. When the mission of the strand is ended, the cord, if non-absorbable, may be removed or allowed to remain as a neutral foreign body. In the case of catgut, as the wound heals, it is disintegrated and taken into the tissues.

The following suggestions follow the lines of established practice in respect to catgut.

The small sized suture is more quickly absorbed under the same conditions than a larger suture. The danger in using a small sized suture, under ordinary circumstances, lies in the fact that it might soften too soon, *i.e.*, lose its function as a suture before the wound had completely healed, and as a result the wound may spread open or "gape".

Chromic or hardened catgut enables the surgeon to use small sizes of sutures without running the risk of their absorbing prematurely.

The following table shows the sizes and kinds of suture material which many surgeons have found to give the most satisfactory results in the different tissues:

Striated Muscle	No. 1 or 2 medium hard
Fascia	No. 0 or 1 medium hard
Skin (through and through)	No. 0 or 1 medium hard or plain, silkworm gut or horsehair
Skin (subcutaneously)	No. 00 extra hard or No. 0 medium hard
Peritoneum (alone)	No. 00 or 0 medium hard
Peritoneum (through and through)	No. 1 or 2 extra hard
Cervix	No. 2 extra hard
Vagina	No. 2 extra hard
Kidney	No. 2 extra hard
Stomach, Intestines, and Glandular Tissue	No. 0 or 1 extra hard re-enforced by silk

Special Sutures—To meet the varying physiological conditions, sutures and ligatures for use in special parts are prepared. For suturing the skin, silk, silkworm gut, or horsehair is usually preferred by surgeons. To meet conditions present in certain forms of operations in the peritoneum an extra hard (forty day) chromic catgut is prepared.

A special form of catgut known as "*obstetrical catgut suture*" is prepared to hold from ten to twelve days.

Tubes of *obstetrical silk* and *obstetrical silkworm gut*, threaded on curved needles, are prepared for those surgeons who do not favor the use of catgut for immediate perineal repair.

For circumcision work, a small size catgut on a curved needle, called a *circumcision suture*, is prepared.

Special sutures are also prepared for use in the cervix, known as *cervix sutures*; for blood vessel surgery, known as *arterial sutures*; for suturing the skin, known as *skin sutures*; for intestinal work, known as *gastro-enterostomy sutures*. Various types of material with needles attached are commonly called *emergency sutures*.

The pharmacist, through a study of the adaptability of the various forms of ligatures and sutures to particular needs, can gain the confidence of his medical patrons by being able to assist them in making their selection of ligature and suture material.

Forms of Enclosure—Ligatures and sutures are supplied in various forms. Catgut, raw, untreated and unsterilized, in strands of ten feet, coiled, silk in skeins or on spools; silkworm gut and horsehair in coils. Prepared ligatures and sutures are supplied enclosed in tubes (see Fig. 762) or in envelopes (see Fig. 763); the tube form being the more largely used. The envelope form of package is prepared as follows:

The ligatures are first wrapped in a piece of manila paper and then in a second piece. The sterilization is done after sealing in two papers or envelopes, and the ligature is not handled thereafter until used by the surgeon. These double-wrapped sutures are then placed in the outer protective envelope.

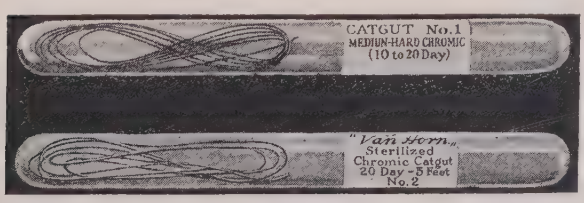
Ligatures in the Operating Room—In handling enveloped ligatures in the operating room, the procedure is usually as follows:

Non-sterilized hands open the papers, touching only one end of the inner paper. The same non-sterilized hand holds the same end of the inner paper while a sterile hand cuts, with sterile scissors, the untouched end of the inner

Fig. 761

Hand spring scale

Fig. 762



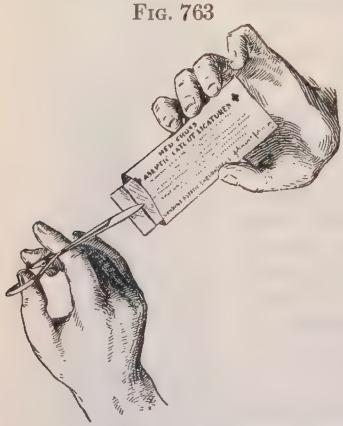
Catgut in tubes

and sterile paper. Following this, a sterile hand with sterile forceps removes the ligature from the cut end of the inner sterile paper.

If the operating room is free from ether vapors, the cut end of the inner paper may be passed through the flame of an alcohol lamp before the ligature is withdrawn. The sterilization of the container is made perfect by burning the end of the paper, and by this means also the necessity of careful handling of the papers, as previously described, is done away with.

In the tube form, the ligature is sterilized and covered with a storing fluid, such as alcohol, chloroform, cumol, etc. The tube is then flame sealed. A file mark carried around the tube permits easy breaking open at that point.

FIG. 763



Catgut in envelopes

A demand has been created for two quite distinct kinds of suture material known as *"boilable"* and *"non-boilable"*. This distinction is important. The terms refer to the manner of disinfecting the outside of the tube. The material inside the tube is intended to be sterile in either case.

The disinfection of the exterior of the tube bears no relation to the sterilization of the contents of the tube.

With the "boilable" tube the outside of the tube may be sterilized by boiling in water, or placing the tube in the steam sterilizer with instruments and dressing.

Tubes labeled "non-boilable" cannot be boiled or subjected to steam sterilization.

The difference lies largely in the storing fluid in the tube. In the "boilable" tubes, this fluid is of such a nature that the tube and its contents are not injured by the heat. In the "non-boilable" tubes, the fluid usually carries a percentage of moisture to keep the ligature soft; hence, boiling or steam sterilization would ruin it.

"Boilable" sutures are the more hard and wiry; "non-boilable" are the more pliable.

The usual method of procedure in boiling the tubes is as follows:

The tubes to be used for the operation are wrapped in a piece of gauze holding all of the tubes necessary for the operation. The gauze enclosed package is then placed in the instrument sterilizer for the usual thirty minutes. The gauze prevents the instruments from striking against the tubes and possibly breaking them. When taken from the sterilizer, the tubes are allowed to cool, after which they are broken in sterile gauze, and the suture removed.

To sterilize the outside of the glass tube containing catgut of the "non-boilable" variety, requires a wholly different process from that which is "boilable". The usual method is to wash the tube with soap and water and immerse it in a disinfecting fluid. The tubes must be weighted down by means of a perforated disk heavy enough to hold them under the solution.

The following solutions have been found to work out satisfactorily for disinfection of the exterior of the tube:

Formulas for Disinfecting Exterior of Ligature Tubes

Harrington's Solution—Mercuric chloride, 185 grains; hydrochloric acid, 2 fluidounces; water, 10 fluidounces; alcohol, 20 fluidounces. Used full strength it will disinfect in ten minutes' exposure.

Mercuric Oxycyanide Solution—One part of mercury oxycyanide to 1000 parts of water. Full strength will disinfect in ten minutes.

Mercuric Iodide Solution—One Gm. of red mercuric iodide dissolved in 5 cc. of a 20 per cent solution of potassium iodide and adding distilled water to make 500 cc. Full strength will disinfect in ten minutes.

Potassium Dichromate Solution—Ten Gm. of potassium dichromate, dissolved in a 10 per cent solution, by volume, of sulphuric acid. A dilution (1 in 10) disinfects in twenty minutes.

Hydrochloric Acid Solution—Hydrochloric acid, diluted 15 parts in 100 parts, disinfects in ten minutes.

Formaldehyde Solution—Thirty parts of solution of formaldehyde to seventy parts of water, by volume, will disinfect in fifteen minutes.

Acriflavine Solution—One part of acriflavine in 1000 parts of water will disinfect in ten minutes.

Softening Catgut

Catgut especially in the form known as "boilable" is stiff and wiry and thus difficult to handle and tie. The strand may be rendered pliable by a short immersion in water or in physiological salt solution. The strand is liable to injury by too long immersion. A second method is by the use of a sterile towel dipped in cold sterile water, or a solution of mercury bichloride, and wrung out by hand. The strands of catgut are laid between the folds of the towel. A third method is immersion in 60 per cent alcohol. By experiments, a minimum and maximum time of immersion can be established. Below the minimum time, the strand is not sufficiently softened; above the maximum time, the tissue is softened too much. The following table may be used as a guide for the immersion of catgut strands by the methods described.

Catgut Immersion

Minimum Time in Minutes

	Size		
	0	1	2
Immersion in water	½	3	4
Between folds of moist towel	3	10	15
Immersion in 60 per cent alcohol	8	15	25

Maximum Time in Minutes

Immersion in water	3	6	8
Between folds of moist towel	10	40	60
Immersion in 60 per cent alcohol	30	50	80

The water should be that which has been sterilized, and should be used at room temperature.

The Bacteriological Testing of Ligatures

It is well within the province of the hospital pharmacist, the laboratory technician, or the pharmacist who has a laboratory, to carry out the bacteriological testing of ligatures.

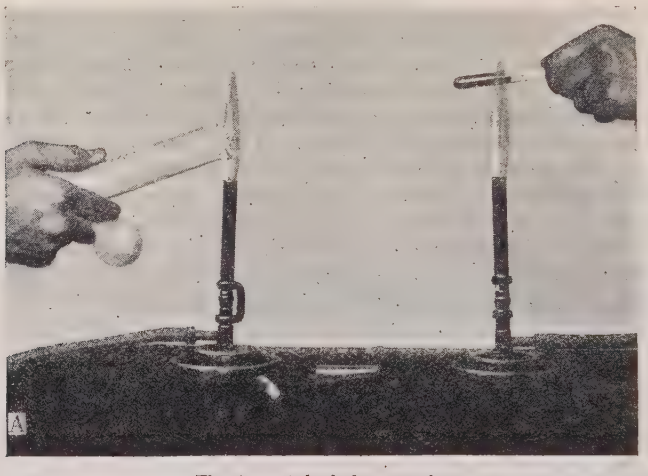
The processes here given are applicable to ligatures and sutures as supplied in the ordinary market forms—sealed envelopes and sealed glass tubes.

The processes involve the placing of the material to be tested in a sterile culture medium, incubating under proper temperature for a suitable period; absence of growth indicates sterility. The entire operation must be conducted under rigid conditions to prevent accidental contamination.

The culture broth is made in the usual manner of beef extract, peptone and salt, and has a slightly alkaline reaction. Each test tube is to contain 75 cc. of broth, previously sterilized, and then incubated at 37.5° C. for five days to make certain of its sterility.

Two operators wearing mouth and nose protectors should work at the transfers. One attends to opening the packages, the other holds the test tube, removes the cotton plug, passes the mouth of the test tube through the flame, heats the forceps in the flame, withdraws the ligature from its container held by his companion, transfers it quickly to the test tube and replaces at once the

Fig. 764



Flaming a tube before opening

cotton stopper. The whole operation must be performed rapidly to prevent accidental contamination.

When testing ligatures in envelopes, the outer printed envelope is removed. The end of the sealed paper within is now torn off, and the inner paper pulled out until its end projects beyond the outer one (see Fig. 763).

The operator now tears or cuts off the end of this inner paper as far as possible from the contained ligature. The cut or torn edge is then set on fire in the flame and immediately extinguished by waving in the air. While this is being done, the other operator, with the test tube in one hand held at an angle and the forceps in the other, has removed the cotton plug, flame-sterilized the forceps and mouth of the tube, and now carefully but quickly withdraws the ligature, drops it at once into the test tube and replaces the cotton plug. This operation is preferably conducted with the hands and arms working inside of a protecting closet.

In opening a glass tube, the tube is first held in the Bunsen flame so that the mark at which it is to be broken and the glass for a short distance on each side of it are enveloped in flame (see Fig. 764). The sterilizing action of the flame is instantaneous. Keeping the fingers as far away as possible from the breaking point, the tube is carefully broken.

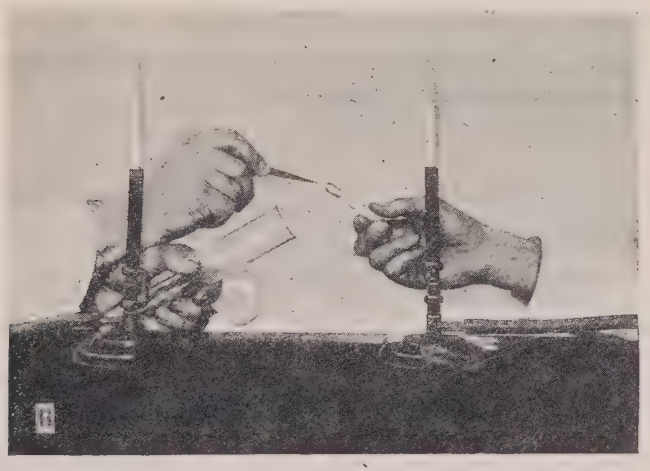
The operator who breaks the tube holds the half containing the ligature so that his companion can seize the strand with flame-sterilized forceps and withdraw it (see Fig. 765). It is then shaken rapidly to remove excess of liquid and dropped at once into the culture tube as previously described.

The culture tubes containing the suture material are now incubated at 37.5° C. for a period of seven days and, if negative, reincubated for another three days.

When making anaërobic tests, the same culture broth is used with the addition, before sterilization, of 2 per cent of dextrose.

Immediately after sterilizing, and while the broth is still hot, add a one-half inch layer of previously sterilized mineral oil (oil sterilized at 163° C. dry heat for one hour) and then incubate them for five days at 37.5° C. to prove sterility.

FIG. 765



Removing ligature for testing sterility

The technic for transferring the material to be tested is the same as for aërobic transfers.

In testing suture material that is stored in a fluid containing an antiseptic such as iodine, bichloride of mercury, biniodide of mercury, etc., use a large volume of broth (400 cc.) in an Erlenmeyer flask. This is done to overcome, by dilution, the inhibitory action of the antiseptic. The manual technic remains the same as described above.

Dispensing Ligatures and Sutures

The dispensing of ligatures and sutures goes beyond simply handing out the strand required by the surgeon. It is a service where technical knowledge is highly essential.

A pharmacist's knowledge must not only apply to prepared ligatures he has in stock, but to all kinds on the market, so that if he cannot supply what the surgeon needs, he can intelligently secure it.

Three or four sizes of catgut and silk ligatures are in far greater demand than other sizes. Silkworm gut, kangaroo tendon, silver wire, and other forms of ligature material are not in much demand in everyday practice.

Manufacturers supply a varied assortment of tubes, bottles, jars, boxes, and paper wrappers containing material ready for use. Ordinarily, two general styles of packing for ligatures—tubes and envelopes—are dispensed. The tubes are usually prepared in three sizes. Large tubes, holding about ten feet of material, intended for cases in which a large amount of a given size is to be used; standard tubes, holding about five feet of material, prepared for general operative work; small (or half-meter) tubes, holding only sufficient material to meet an emergency, or where an extra ligature is required to finish an operation.

Cautions—Sterile suture material, like sterile dressings should always be stored in a clean, cool, and dry place.

In storing catgut or silk ligatures in envelopes, dampness and moisture must be guarded against.

The individual tubes or envelopes should always be kept in their containers and never allowed to lie about indiscriminately either in a drawer or on a tray or a shelf.

The dispensing of such highly specialized products as ligatures and sutures calls for the most painstaking intelligence and care.

CHAPTER CXII

STERILIZATION AND STERILE SOLUTIONS

The extensive use of sterile solutions, preparations and dressings in medical practice and the large application of the principles of sterilization to manufacturing processes, for the purpose of preserving products from decomposition, have made it necessary that the pharmacist be familiar with these processes and in many instances apply them. The United States Pharmacopœia and the National Formulary have both included a brief consideration of sterilization and contain preparations which must be sterilized. Those who assume the responsibility for the preparation of sterile products must, at the very outset, be impressed with the importance of a thorough preliminary training in the technic of bacteriological practice. Many operations require the most exacting care and training for their successful accomplishment. What is presented here is largely suggestive, and space cannot be taken for that intricate detail which is necessary. The pharmacist who would add this service to his other professional duties is therefore urged to secure laboratory training in general bacteriological methods before undertaking work along this line.

The pharmacist will also often handle sterile products, prepared in special laboratories, and it is important that he should know and always remember that they remain sterile only so long as they are properly protected from contamination. No wrappings should be removed, or seals broken, or containers opened until ready for use. The responsibility in dealing with this class of preparations is very heavy, as often life itself may depend upon the product being properly sterilized and then kept in that condition until used.

Portions of the U. S. P. and N. F. articles on sterilization are incorporated in the following:

The term Sterilization, as used in medical or pharmaceutical practice, means a process whereby the destruction or removal of all microscopic living organisms and their spores is accomplished. Some bacteria, under certain conditions, undergo a transformation into a resting stage, when they are called spores. In the spore state they are able to resist influences which would kill the bacteria. Most disease-producing bacteria do not form spores and are therefore comparatively easily killed. The anthrax and tetanus bacilli are exceptions to this, as their spores are quite resistant. An object which is free from living microörganisms is spoken of as being "sterile", but this condition can be maintained only so long as the necessary precautions are taken to prevent contact with the atmosphere or other media or apparatus which may carry microörganisms.

The uses of sterilization, as applied by pharmacists, are:

1. For the preparation of solutions for hypodermic injection.
2. For the preparation of aseptic medicines for internal or external administration.
3. For the preparation of solutions, dressings, etc., for surgical use.
4. For the preservation of preparations or substances through the destruction of organisms which would otherwise cause deterioration or decomposition.

There are various methods whereby sterilization may be accomplished, and it is necessary that the operator shall select in each case the one which is most suitable.

From the viewpoint of the pharmacist it is important to know:

First—That most microörganisms multiply rapidly at temperatures between 20° and 40° C. (68° and 104° F.) if there is some nutritive material present.

Second—If contaminated substances are maintained at a temperature of freezing (0° C. or 32° F.) or below, the development of organisms is retarded, but they are not necessarily destroyed.

Third—All classes of microörganisms, whether they are bacteria, molds, yeasts, diatoms or protozoa, also their spores, may be destroyed by practically the same procedure. Any method which will kill all bacterial spores will also destroy every form of life.

Fourth—Bacteria may develop in almost any substance if sufficient moisture and atmospheric oxygen are present and the temperature is favorable. Some bacteria are anaërobic, that is, they do not require oxygen, and will not survive in its presence.

Yeasts develop in saccharine substances, while molds develop within and upon a large variety of organic substances. Protozoa and diatoms may occur in water which is highly contaminated with organic matter. Bacteria and molds do not thrive in sunlight, while diatoms and algæ generally develop best in sunlight.

Fifth—Bottles, flasks, test tubes, etc., stoppered with purified cotton (which has been wrapped in gauze to prevent contamination from filaments of cotton, and afterwards passed quickly through a flame to burn off any loose filaments on the gauze), then sterilized and kept dry, may be maintained in a sterile condition for an indefinite period. Before opening, however, the orifice should be sterilized by passing it through a Bunsen flame. The exterior of the cotton plug is burned off at the same time, thus destroying bacteria which may have lodged there.

Sixth—It is desirable that the pharmacist should operate, while preparing sterilized solutions, ointments, etc., under conditions which will avoid the possibility of the contamination of the material, apparatus, etc., by the falling of dust during the operation.

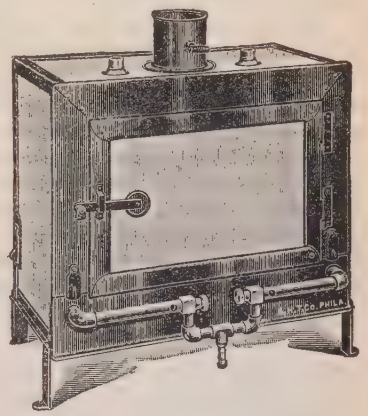
Seventh—Bottles containing sterilized liquids to be dispensed should be closed with rubber stoppers which have previously been sterilized by boiling for ten minutes in a 5 per cent phenol solution, then thoroughly rinsed in boiling water and stored in alcohol until used. These should be handled only with large forceps, the tips of which have been sterilized by heating in a Bunsen flame.

Eighth—Sterilized freshly distilled water should be used in preparing all aqueous solutions. It should be prepared as follows: Place the necessary quantity of freshly distilled water in a flask of Jena or other so-called "non-soluble" glass, which has been previously cleansed and sterilized as described for glassware, under *Dry Heat*, page 1781. Close the mouth of the flask with a pledget of sterilized purified cotton (which has been wrapped in gauze to prevent contamination from filaments of cotton and afterwards passed quickly through a flame to burn off any loose filaments on the gauze), boil the contents for one hour, or sterilize it in an autoclave at 15 pounds' pressure for twenty minutes. Then allow it to cool without removing the cotton plug. Finally protect the mouth of the flask and the cotton stopper from infection with dust by wrapping it in sterilized paper. For use in hypodermic injections only freshly distilled water should be taken, and it should be used within forty-eight hours after sterilization (see *Aqua Destillata Sterilisata*, page 1795).

The methods by which sterilization may be accomplished are as follows:

Direct Flame (Flaming)—It is sometimes possible to make use of the direct application of the flame of the Bunsen or Meker burner (see Figs. 69, 71 and 72) for sterilization, when the object will not be injured. Such objects as platinum needles, dry pipettes, the metallic orifice of a Berkefeld-type filter, the lip of a bottle or test tube, the points of tweezers or forceps used for handling sterilized rubber stoppers, the walls of a metallic closet, etc., may be sterilized by holding them within the Bunsen or Meker flame for about ten seconds or playing the flame over them a few times.

Fig. 766

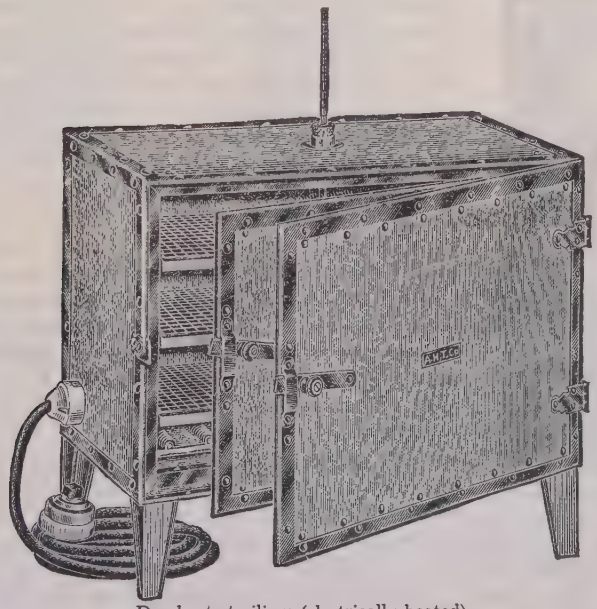


Dry heat sterilizer (gas heated)

Dry Heat—This method requires that the object be heated in an oven or other suitable apparatus (see Figs. 766 and 767) at a temperature of from 160° to 170° C. (320° to 338° F.) or at even higher temperatures, continued for at least two hours. It is desirable that the object be wrapped in paper so that it may be afterwards handled and stored in a sterile condition. Slight browning or charring of the paper is not objectionable, and is one of the indications that the proper temperature has been reached.

This process may be used for the sterilization of empty flasks, ampuls, bottles, funnels, test tubes, Petri dishes, ointment jars, and other glassware,

Fig. 767



Dry heat sterilizer (electrically heated)

but should not be used for any substance which may be injured by the high temperature required.

Bottles and other glassware which are to be sterilized should be thoroughly

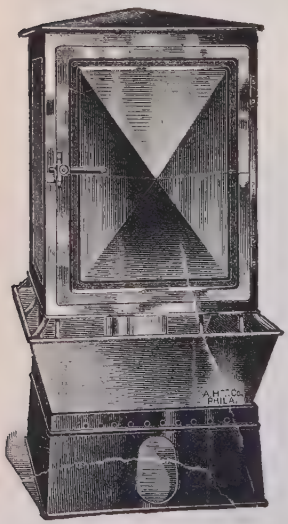
cleansed to remove all organic matter, afterwards rinsed with very weak hydrochloric acid (about 0.3 per cent) to neutralize the alkalinity of the glass, then with distilled water until the washings are neutral and, after drying, stoppered with purified cotton, and finally wrapped in paper and heated for one hour at about 180° C. (356° F.).

This method may also be used for the sterilization of petrolatum, fixed oils, lard, and many powders as talc, kaolin, boric acid, zinc oxide, and others which are not injured by this temperature, the precaution being taken, however, to spread them out in a thin stratum, about 6 mm. (¼ inch) in thickness, so that the heat may penetrate.

In sterilizing petrolatum and fixed oils, apply the heat directly to a sand bath carrying the vessel containing the substance, raise the temperature of the oil to 200° C. (392° F.), and then immediately withdraw the heat and protect the sterilized product from contamination. Glycerin should not be heated higher than 150° C. (302° F.) and this temperature should be maintained for one-half hour. Volatile substances, such as Camphor Liniment, for example, should be placed in strong bottles, such as solution of magnesium citrate bottles, with the stoppers fastened in, or they should be placed in ampuls and sealed, and the containers and contents heated in an oil bath or a concentrated, aqueous calcium chloride solution to a temperature of about 121° C. (249.8° F.) for one hour.

Moist Heat at 100° C. (212° F.)—The use of live steam for sterilization, usually in an Arnold sterilizer (see Fig. 768) or in a covered kettle or boiler, is more generally applicable than dry heat. On account of the greater penetrating power of steam than that of dry heat a lower temperature is equally efficient for sterilization. By this process the substance to be sterilized is sometimes heated but once in live steam, the treatment continuing for from thirty minutes to one hour, but "interrupted" or "fractional" sterilization is preferable, due to the fact that many substances are injured by prolonged heating, and especially because organisms may exist in the spore stage and in that condition will not be destroyed by the first heating. For the application of "interrupted" sterilization, the substance is heated in live steam, after the temperature has been raised to 100° C. (212° F.) for fifteen minutes each day on three successive days, the substance being kept during the resting period between the heatings at a temperature of about 20° C. (68° F.). The "moist heat" sterilization at 100° C. (212° F.) may be used for many pharmaceutical solutions, such as some eye waters, gargles, and similar solutions, some medicinal syrups, mucilages, etc. This method may also be used for the sterilization of collapsible metal tubes.

Fig. 768



Arnold steam sterilizer

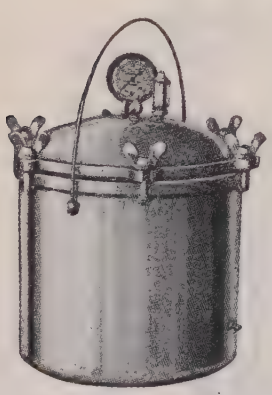
Materials or utensils to be sterilized should not be packed in the sterilizer too tightly, whether dry heat or steam is used. They should be placed in the sterilizer in such a manner as to insure free circulation of the heat and with due regard to the possibility of the heat reaching every portion of the material to be sterilized. When sterilizing empty, plugged test tubes, flasks, etc., they should be placed so that the stoppers are downward to insure more rapid and complete evacuation of the contained air.

Much of the pharmaceutical glassware on the market is relatively quite soluble in water. When solutions are sterilized in glass vessels of this character, a copious precipitate appears on cooling, together with a clouding of the glass, and in the sediment may be seen glistening spicules or thin flakes. It is therefore advisable to use vessels made of one of the varieties of glass known as "non-soluble".

For the preparation of sterile solutions for subcutaneous, intramuscular or intravenous administration all glassware used in preparing the distilled water, the making of the solutions, and the filling, and the ampuls themselves, must comply with the test for alkalinity in the glass as given in detail under *Selecting Ampuls*, page 1791. If such glass is employed this method may be used in sterilizing solutions for culture media, caffeine, caffeine salicylate, caffeine benzoate, sodium arsenate, sodium cacodylate and the mineral acid salts of strychnine, morphine and cocaine.

Steam Under Pressure—For laboratory purposes this form of sterilization has many advantages. Its application by the use of a steam cylinder, known

FIG. 769

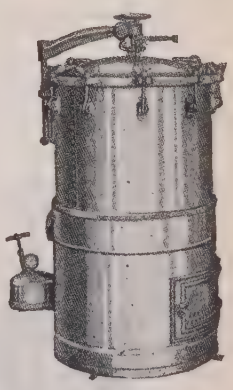


"National" aluminum high pressure sterilizer

FIG. 770

"Pressure cooker" which may be used as an autoclave

FIG. 771



"National" autoclave (may be heated with gas, steam, or by gasoline burner)

as an autoclave (see Figs. 769 to 773), produces results from one heating of twenty minutes, under a pressure of one atmosphere [a temperature of about 121° C. (249.8° F.)], which are more reliable than the method requiring heating at 100° C. (212° F.) each day for three successive days. The higher temperature, however, must again be considered and the method cannot be used for substances which are injured by this degree of heat. The process is well adapted to the sterilization of solutions of stable salts, etc.

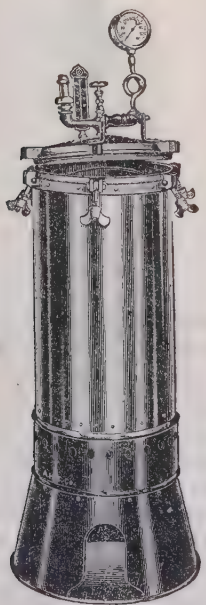
Some autoclaves are operated by live steam generated from an outside source, while in others the steam is generated by heating water placed in the bottom. The latter type is most common and is most generally employed in smaller laboratories. After placing water in the autoclave the material to be sterilized is placed in position on shelves or trays above the water. The door or top is closed and securely fastened, the air valve is opened, and heat is applied. As steam is generated, the air is forced out of the air valve and when all air has been expelled, the air valve is closed and the steam pressure allowed to increase until the desired pressure or temperature is reached.

Below is given a table of pressures and the corresponding temperatures for "saturated steam".

Pounds pressure	Degrees F.	Degrees C.	Pounds pressure	Degrees F.	Degrees C.
0	212	100	12	244	117
2	218	103	14	248	120
4	224	107	16	252	122
6	230	110	18	255	124
8	235	112	20	259	126
10	239	115	22	262	128

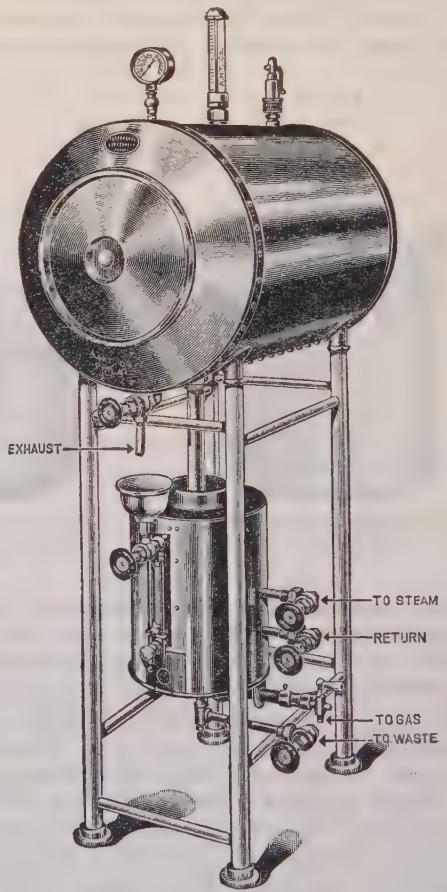
The safety valve should be set for the desired steam pressure or the source of heat should be regulated so as to maintain the desired pressure. After the pressure has been continued for the desired length of time the heat is withdrawn and the autoclave allowed to cool. When the pressure is reduced to 0 pounds, the air valve is opened slowly and air admitted. The autoclave may then be opened and the material removed. Should the air valve be opened quickly to hasten the reduction of steam pressure, there is danger of liquid materials boiling over in the autoclave and cotton plugs in test tubes, flasks, etc., are likely to be blown out. The "National" sterilizers are manufactured by the Northwestern Steel and Iron Works.

FIG. 772



Vertical autoclave

FIG. 773



Horizontal autoclave

Stoppers—Cork stoppers should not be used for containers to be sterilized. Cotton stoppers may be employed, and when used may be wrapped in a layer

of gauze and covered with stout paper or tinfoil as described under *Aqua Destillata Sterilisata*. Rubber stoppers should be wrapped and should be sterilized separately or attached to the outside of the necks of the containers. These stoppers should be long enough so that they may be inserted and removed without touching the lip of the container with the fingers. The sterilized wrapper of the stopper may be used as a cap. Glass-stoppered containers are sterilized preferably by dry heat, capped, and the stopper separated from tight contact with the neck of the container by a strip of paper.

Articles Made of Rubber—Rubber tubing and rubber stoppers should not be sterilized by hot air, but by steam under pressure, with the precautions indicated above, or by boiling for thirty minutes in a 2 per cent aqueous solution of cresol or phenol.

Medicinal Substances Not Easily Decomposed by Heat—If in aqueous solution, these substances should be sterilized by steam under pressure. In order that the exposure to heat may be the shortest which will effect thorough sterilization, the container should not be of thick glass and should be of as small a capacity as can conveniently be used. The preliminary heating before the temperature of 121° C. (249.8° F.) is reached may be shortened by admitting the steam to the autoclave under pressure from a separate generating plant, delivering a pressure constantly above eighteen pounds. The stoppers should be of cotton, as above described, and a wrapped rubber stopper should be attached to each container unless the contents are for immediate use.

If the substances are dry or oily, they should be sterilized by dry heat, preferably in glass-stoppered containers, as described under *Glass and Metal Utensils*. Cap the utensil or container with parchment paper before sterilization for protection against contamination and do not remove the paper until the substance is to be used.

Surgical Dressings—Cotton, bandages, gauzes, ligatures, etc., may be rendered sterile by treatment with steam in a pressure apparatus (autoclave) at 121° C. (249.8° F.) for twenty minutes or by exposure to dry heat in an ordinary air-bath or sterilizer at a temperature of from 160° to 170° C. (320° to 338° F.) for two hours. It should be remembered that all surgical materials are not amenable to such thorough treatment without more or less deterioration taking place. Bandages must be folded or packed in such a manner as to permit the penetration of steam or dry heat during the process and should be so arranged that after the sterilization is completed all subsequent contamination with bacteria will be prevented. This is usually accomplished by immediately enclosing them in glass containers or wrapping them in a number of thicknesses of previously sterilized parchment paper.

Low Temperature (Pasteurization)—This process is carried out in practically the same way as described on page 1782 [interrupted sterilization with moist heat at 100° C. (212° F.)], except that the temperature is maintained at from 60° to 70° C. (140° to 158° F.).

Material to be sterilized at pasteurization temperature is heated on six successive days for from one-half to one hour each day at the temperature indicated above, and during the resting stage between the heatings, kept at about 20° C. (68° F.).

This method is employed when the material to be sterilized is readily decomposed by heat, and it is recommended for the sterilization of solutions of organic salts, alkaloids, alkaloidal salts, and such other substances as are subject to decomposition by exposure to a higher temperature.

Filtration—This method, when suitable apparatus is used, affords one of the most practical and efficient processes for preparing sterilized solutions

A Berkefeld or Chamberland type of filter candle, which is made of stone or porcelain, is so arranged that the orifice projects from the bottom of a glass or metallic cylinder, a metallic bell being attached above and around the outlet. To hasten the operation, the jar may be arranged so that it can be closed and air pressure applied over the liquid to be filtered. Pressure may be applied by a rubber bulb or hand pump through a tube fitted with a stopcock. When the pressure has been applied the stopcock may be closed and the filtration allowed to proceed.

To use this apparatus it is supported on a tripod or retort stand, the metallic orifice and inside of the bell cover sterilized by the direct application of the Bunsen flame; the lip and cotton stopper of the sterilized vessel also flamed, the cotton plug removed and the bottle slipped over the outlet from the filter. The liquid to be sterilized is then poured into the jar, the pressure applied, and when all of the liquid has filtered into the bottle, the latter is closed with a sterilized stopper.

The more customary procedure, however, is to connect the outlet of the filter, by means of a tightly-fitting stopper, with a sterile, hard glass flask, having a side tube. A vacuum is then applied to the side tube to hasten the filtration. When the filtration is completed the air is admitted slowly through a wash bottle or through a good air filter to prevent contamination by the inrush of dust-ladened air.

If a large tube having a stopcock at the top is inverted over the filter candle in such a manner that the liquid may be drawn in at the bottom when the apparatus is filled, and the stopcock opened, the liquid will completely immerse the filter candle (see A Fig. 780). When the stopcock is closed and the filtration is allowed to proceed, the filter candle will remain completely immersed until practically all the solution is filtered. Otherwise, if the filter jar is not full, the efficiency of the filter candle is materially reduced.

When filtering solutions of mercury salts, etc., which are injured by contact with metal, the vacuum system is especially to be recommended and the metal parts of the filter should be dipped in melted paraffin so that they may be covered with a thin coating of paraffin. A Berkefeld filter without metal parts may also be used. The Berkefeld filtering apparatus should be taken apart after each operation and the candle filter thoroughly cleaned. This may be accomplished by forcing water through the filter from the inside outward and scrubbing gently with a stiff brush, after which it should be connected as for filtration and a quantity of distilled water allowed to pass through. After careful washing, the filter candle should be sterilized in an autoclave, or by heating at 100° C., in live steam or boiling water, during one hour. The candle should be frequently tested by placing the entire candle under water and forcing air through it by means of a rubber bulb or a pump. By this means a break or crack is easily detected. Types of filter candles and methods of using are shown in Figs. 774, 775, 780 and 787.

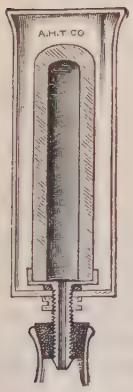
This device may be used, if the proper precautions are taken, for aqueous solutions such as gargles, eye washes, solutions of alkaloids, etc.

Extemporaneous Sterilization—It may become desirable, when time is not available or when substances are easily injured by heat, to prepare solutions or preparations which are approximately sterile. If this method is to be used it is essential that distilled water, the several sizes of bottles, funnels, filter paper, rubber stoppers, ointment vehicles, ointment jars, collapsible metal tubes, etc., be kept on hand in a sterile condition.

The operator may conduct the necessary manipulation within a large sheet iron oven, the door of which is open and the interior of which has been ster-

ilized with a Bunsen flame, or under a glass box which has been cleansed with alcohol and chloroform, or under a cloth canopy stretched on a wooden frame, the cloth immediately before use being moistened with five per cent phenol solution. All weighings and operations should be carried out under the protected area. Weighings should be made on glass scale pans which have been first cleansed with alcohol and afterwards with chloroform, or on metallic pans which have been sterilized in a Bunsen flame. If a spatula is to be used it should be treated with alcohol and chloroform or passed through the Bunsen flame several times.

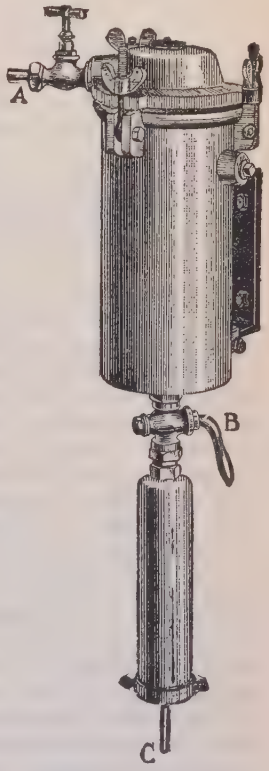
Fig. 774



Candle filter

If an aqueous solution is to be prepared, the material is weighed and transferred to a sterilized bottle, the mouth of which has been sterilized in the flame before removing the cotton plug, the sterilized water is then added and the bottle stoppered with a sterilized stopper. Chemical salts and other substances which are likely to be used for making sterile preparations by this method should be procured especially for this work, and should be carefully protected from dust and other contamination. If a solution requires filtration, this can be done in the protected area, using a sterilized funnel and sterilized cotton or filter paper, which has been thoroughly washed with alcohol. Ointments, powders, etc., may be mixed within the protected space, using sterilized materials, apparatus, and containers. It must be remembered that this operation results in only approximate sterility, and that freedom from dust in the room, personal cleanliness of the operator, and the most scrupulous care throughout are required for satisfactory results.

Fig. 775



Filtering under pressure

This process is the one used in the preparation of Salvarsan or "606".

Emulsions in Glycerin or Oil—Approximately sterile solutions or emulsions in glycerin or oil may be prepared in the following manner: Heat glycerin or oil in flasks of thin glass containing not over 50 cc. each, for two hours at from 120° to 130° C. (248° to 266° F.) in a dry air sterilizer, then introduce the sterile or approximately sterile medicinal substances after the liquid has cooled. The desired medicament may be incorporated by triturating it with a sterilized pestle in a mortar containing the previously sterilized medium (glycerin or oil) and the solution or emulsion should then be quickly transferred to a sterilized glass container.

Sterilization by Means of Chemical Agents—For the purpose of assisting in sterilization or of protecting substances from subsequent contamination, chemical agents are sometimes employed.

Dependence solely upon chemical germicides demands larger proportions of these than are usually allowable; hence they should be used as adjuncts only, and generally in quantities insufficient to insure sterility in themselves.

When chemical agents are employed, the usual precautions should be

observed as to cleansing and sterilizing bottles, graduates, stoppers, etc., and in so far as possible without injury, the substance itself should be sterilized or pasteurized by heat. The chemical agents should be only used to assist in the processes and to hinder subsequent contamination.

This method is frequently used for:

1. The disinfection of the hands and the table before the preparation of a sterile solution.

2. For the disinfection of scale pans and spatula, etc., alcohol, ether, or chloroform chiefly being used for this purpose; but sterilization by heat is better.

3. To sterilize large glass vessels that cannot easily be subjected to heat—such as carboys, large bell jars, etc.

4. To maintain in a sterile condition various agents such as antitoxins, bacterial vaccines, etc.

For the preservation of antitoxins and bacterial vaccines, phenol or cresol is used, the former in the proportion of 0.5 per cent, the latter from 0.25 per cent to 0.4 per cent. Cresol is from two and a half to three times as strongly germicidal as phenol and no more poisonous. While other chemical germicides may be used, these have been preferred because they are uniform and relatively non-toxic.

It is impossible to set definite limits which will fit all cases for the amounts of the chemical agents which may be employed, because the composition of the substance and its degree of contamination are important factors in sterilization.

Solutions of salts, practically free from organic matter, are easily sterilized, while solutions which contain appreciable, though small, amounts of organic substances may be difficult to sterilize.

Mineral acids, while objectionable as disinfectants in pharmaceutical preparations, inhibit the development of germs in very weak solutions, and acid solutions sterilize more easily than do neutral or slightly alkaline solutions.

Iodine is one of the most effective of disinfectants, and preparations containing free iodine in material proportions become sterile of themselves. The same is true of solutions containing chlorine or hypochlorites, or bromine. The chlorides, bromides, and iodides in general have only very feeble disinfecting power, but the soluble fluorides are active.

Chlorine and the hypochlorites, also bromine, have long been used as disinfectants, but because of their irritant properties their use was restricted. Now, however, various non-irritant chlorine compounds are being largely used in surgery, in the treatment of wounds, and in water sterilization (see pages 547 and 570).

The salts of mercury and of silver are active germicides and are among the most important disinfectants for physiological use, but they have specific actions which limit, or may prohibit, their addition to pharmaceuticals for antiseptic or disinfectant purposes. Salts of copper are powerful fungicides, but are feeble antiseptics. Other neutral salts are feebly antiseptic and not generally of value for this purpose.

Peroxides, when under conditions in which they liberate nascent oxygen, may sterilize, but are useful only in proportion to their own decomposition. Similar powers are attributed to persulphates and permanganates, which act by liberating nascent oxygen, and which require an intimate contact with the substance to be sterilized to be effective.

Of the organic bodies, alcohol stands first in pharmacy as a preservative. Alcohol, when present to the extent of from 20 to 40 per cent by volume, is an

efficient antiseptic. Solutions containing from 40 to 80 per cent are actively disinfectant, the latter strength being most efficient. Above 80 per cent its efficiency tends to diminish, and stronger alcohol may preserve without killing the microörganisms.

Formaldehyde is one of the most efficient of disinfectants (see page 1866), and is antiseptic in very small proportions, but may be objectionable for pharmaceutical preparations.

Chloroform and bromoform are both active germicides in aqueous solutions while iodoform is employed medicinally for this one purpose. Thymol iodide is another instance of like character.

Phenol is perhaps the most common of disinfectants, and with cresol is the substance most frequently used in hypodermatic and epidermatic medicaments. These have the advantage of combining activity with stability. Other phenolic compounds, as resorcinol, thymol, betanaphthol, phenyl salicylate (salol), etc., are useful agents and are frequently used in medication for their antiseptic qualities.

Chlorbutanol (see page 861) is also used for the preservation of some solutions intended for hypodermic injection and has the added advantage of its local anesthetic action.

A number of the volatile oils, as anise, clove, cinnamon, pine, gaultheria, etc., possess appreciable value as antiseptics, and, while used mainly as flavors, are also employed for their antiseptic actions. Benzoic and salicylic acids are often preferred for internal administration. They are efficient as antiseptics, but are feeble as disinfectants. In foods benzoic acid is limited, by food commissioners, to one part per thousand, which is not sufficient for sterilization, but which inhibits the development of most germs.

If the responsibility is thrown upon the pharmacist, the first consideration should be the character of the substance to be sterilized, the presence of antiseptic ingredients, whether active or feeble, being considered, and the action of heat upon them. Heat sterilization should always receive first consideration.

If pasteurization only is allowable, the use of 0.5 per cent to 1 per cent of phenol will aid materially in insuring sterility, since all germicides are much more efficient at high than at low temperatures. Cresol, in 0.1 to 0.4 per cent solution, is also frequently used. These proportions may not be sufficient in themselves to produce sterility, but they are aids in securing and maintaining this condition, and are usually preferred in preparations for hypodermatic and epidermatic medication.

For sterilizing medicinal substances for internal administration hydrogen dioxide, sulphurous, salicylic or benzoic acid should be first considered. One part per thousand is the common limit for these, excepting hydrogen dioxide. The latter is often efficient in very small proportions (one in ten thousand), but is slow in action and of little value in mixtures or for preserving preparations used intermittently. It has the advantage of not seriously disturbing digestion.

The use of chemical disinfectants or antiseptics and the problems of sterilization call for judgment and some knowledge of the principles involved. No definite procedure can be recommended which will fit all cases. Success in sterilization must depend, as in other things, upon an intelligent application of principles rather than upon a literal following of arbitrary rules.

The use of the ultraviolet ray for the sterilization of water is also employed in large laboratories and hospitals. The water is passed through a special apparatus where it is exposed to the ultraviolet ray, which causes the destruc-

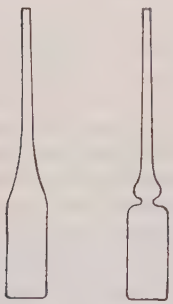
tion of all bacteria. An apparatus carrying one 110-volt lamp is capable of sterilizing 150 gallons of water per hour.

Pasteurizing Milk—When milk is heated at low temperatures (between 50° and 80° C. or 122° and 176° F.) for from twenty to thirty minutes, most of the bacteria are destroyed without altering the nutritive quality of the milk. In many communities pasteurized milk may be obtained from milk dealers, but it may be readily prepared in the home by placing the milk in suitable bottles, usually the regular, round milk bottles used for infant feeding, holding from six to twelve fluidounces, stoppering them with absorbent cotton, placing them in a frame holding six or more bottles and this in a kettle of water. The water and milk are then heated to the desired temperature, usually between 65° and 70° C. (149° to 158° F.), then allowed to stand, without further heating, for from twenty to thirty minutes, and afterwards quickly cooled. The milk should be kept in the bottles in which it was pasteurized, preferably on ice, until used.

STERILE SOLUTIONS

The use of sterilized medicinal solutions or suspensions, usually intended for hypodermic injection, either subcutaneously, intramuscularly, or intravenously, has become very popular in recent years and the number of medici-

Fig. 776



Varieties of ampuls

Fig. 777

Ampul vial

Fig. 778

Bulk container for sterile liquids

nal preparations prepared in this manner is constantly increasing. The popularity of this form of medication is due largely to its convenience to the busy practitioner, the ease with which sterile products may be preserved and handled, and the advantages obtained with minimum dosage and rapidity of action without impairing the patient's digestive mechanism and without the digestive secretions impairing the action of the medicament.

These solutions are prepared for dispensing in hermetically sealed containers of several types as follows:

Ampuls—This is a term applied to small, flask-shaped glass containers (see Fig. 776), which after filling, are sealed by melting the glass at the tip until it fuses. The name is derived from the Latin *Ampulla* meaning flask.

Ampul Vials—These are small vials (see Fig. 777) usually made from glass tubing and sealed with a rubber stopper which may be punctured with the needle of a hypodermic syringe when it is desired to withdraw the solution.

Bulk Containers are vials or bottles (see Fig. 778) made of the same high quality of glass as ampuls or ampul vials and are closed with a puncturable

rubber diaphram which is preferably held in place by a metal cap either screwed or crimped on. With the latter container, the physician may withdraw a number of doses, for testing the patient's tolerance to the drug and for graduating the dose according to their susceptibility, without the loss of material.

Selecting the Empty Ampuls—The first consideration is the containers. While these may be made by the pharmacist, when sufficiently skilled, from glass tubing, the better plan is to buy them from regular glass blowers. The kind of glass from which they are made is, however, of great importance. Common flint or bottle glass, or even the usual glass for chemical apparatus, is too soluble and alkaline for many substances. They should be made of a colorless, so-called "hard" or "non-soluble" glass. The ordinary amber glass is not well suited as it is exceptionally soluble, but a tinted glass has been produced which is non-soluble and also excludes the more powerful light rays. If protection from light is required, this may be secured by enclosing the filled ampuls in suitable boxes.

The glass used for ampuls should pass the following test for solubility and reaction prescribed by the N.F. V. Dissolve 0.005 Gm. of phenolphthalein in 0.5 cc. of neutral alcohol and mix this solution with 100 cc. of distilled water. Fill the ampuls to be tested with this solution, seal them, and then immerse them in live steam or boiling water for six hours. After cooling, the content of the ampuls must show no pink color and no loose scales or flakes of glass.

Fig. 779

Filling ampuls

Ampuls may be cleansed and sterilized as follows: A piece of rubber tubing is fitted to a large-bore hypodermic needle and is securely tied on. The other end of the tubing is fitted to the spigot of a hydrant and water is run into the ampuls by introducing the needle into them and allowing the water to run freely until the ampul is thoroughly cleansed. The ampul is emptied by the use of an atomizer bulb which is connected to another hypodermic needle by means of which the water is sucked or blown out of the ampul.

The washing of ampuls with a dilute acid solution (0.3 per cent hydrochloric acid) and then thoroughly washing with distilled water until all traces of the acid are removed, has a tendency to neutralize the alkalinity of the glass and prevent precipitations which might otherwise occur in the ampul.

The ampuls are then placed in wire baskets and sterilized by heating in an oven for one hour at a temperature of 180° C. (356° F.) after which they are carefully protected from contamination until filled and sealed.

Filling Ampuls—Many ingenious devices have been offered for filling ampuls. One general plan calls for the inversion of fifty or more empty sterile ampuls in a sterilized jar, the pouring on top of them of just sufficient of the sterile solution to fill the ampuls, then the creation of a vacuum in the jar and ampuls by means of a suction pump, followed by the slow admission of air through a cotton filter. The air pressure forces the solution into the ampuls, which may then be quickly sealed.

Another plan is illustrated in Fig. 779. Here the solution is sterilized by filtration through a candle filter located at the top of the apparatus, and is received in the sterilized glass reservoir below. By turning the stopcock the amount for each ampul may be measured in the graduated cylinder on the side and by another turn of the stopcock the liquid is delivered into the ampul

below, which is subsequently sealed. This apparatus is expensive, difficult to sterilize, and very slow in operation. Machines are being automatically operated on a large scale whereby sterile ampuls are filled, individually, as each passes a certain point on the outer edge of a revolving disk. At this point a syringe, similar to a hypodermic syringe, delivers the measured volume of sterile solution inside the ampul. As the disk revolves another empty ampul moves into position for filling, while the filled ampul is sealed, then removed, and its place taken by a fresh, empty ampul. The pharmacist, however, is not likely to equip himself with elaborate apparatus for doing this work, especially when a burette having a glass stopcock and with a large bore hypodermic needle attached to the lower orifice by means of a piece of rubber tubing will be found very satisfactory for filling ampuls. Having sterilized the empty ampuls, the burette, and the solution or suspension, and set up the apparatus in a protected area where it is not likely to be contaminated by falling or floating dust the ampuls may be readily filled. The needle should be plunged inside the ampul to a point below the neck, so that the air may escape and the neck remain dry for sealing. For viscous solutions a hypodermic syringe, preferably of veterinary size with a barrel, may be employed in the same manner. When filled, the ampul is sealed by holding it in a Bunsen burner at an angle, so that the contents do not run into the neck of the flask, and slowly rotating it continuously, so that as the glass melts it tends to turn inward, sealing the neck with a bead of glass. If available, a blast lamp is to be preferred for the sealing, as non-soluble glass melts slowly in the Bunsen flame. In whatever manner it has been filled, it is best to sterilize the sealed ampul again to insure a perfect product.

Many of the devices offered for filling ampuls have been found upon application to be impractical, due either to the fact that they are expensive, slow in operation, difficult to clean, difficult to sterilize, or that with their use it is difficult if not impossible to prevent contamination. The apparatus described below has been designed by Gilbert L. Harvey, after using a number of these devices and has been found to be practicable.

The use of this apparatus is as follows: After cleansing the hard glass, receiving bottle, it is rinsed with dilute hydrochloric acid (0.3 per cent) and then thoroughly with distilled water. The neck is fitted with a rubber stopper having two perforations of suitable size. Through one opening is forced a glass tube reaching to the bottom of the bottle and through the other is forced a bent glass tube reaching just through the stopper (see Fig. 780). To the top of the long tube is fitted a piece of rubber tubing two or three inches long which has been heated in an autoclave and then thoroughly washed with dilute ammonia water to remove the "bloom", and afterwards with dilute acid and distilled water. The end of the long glass tube is carefully wrapped in gauze and to the end of the bent glass tube is attached an air filter D. The receiving bottle is then sterilized in an autoclave.

The air filter, just referred to, may be constructed by packing a glass tube of from 6 to 8 inches in length and 1 inch in diameter, with gauze and inserting perforated rubber stoppers in both ends. Small glass tubes are forced through the openings in both stoppers.

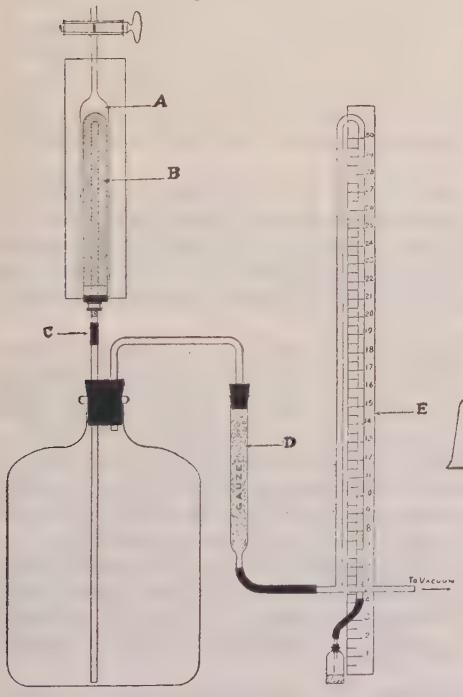
When ready for use, the gauze wrapping on the long tube is first "flamed" to destroy bacteria which may have lodged there, and then removed and the rubber tubing connected to the orifice of a previously sterilized, Berkefeld-type filter, care being used to prevent contamination.

The solution is then filtered into this receiver. If the vacuum method of filtration is used, a vacuum pump is connected to the end of the air filter.

When filtration is completed, the vacuum is broken by permitting the air to slowly enter the receiver through the air filter. The receiver is now carefully disconnected from the filter and connected to the previously sterilized filling attachment, the parts being quickly "flamed" and care being used to prevent contamination in so doing.

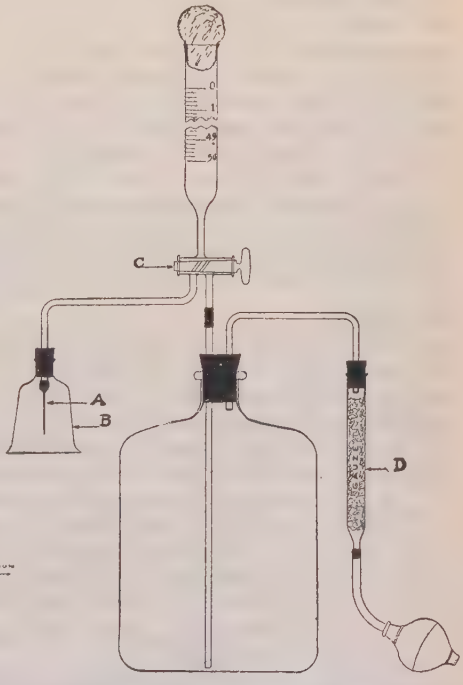
The filling attachment consists of a graduated burette with a two-way stopcock. The tube used for the inlet is left straight and the tube used for the outlet is bent at right angles, first outward, and then downward. A glass bell is fastened to the outlet tube by means of a rubber stopper to prevent dust or microörganisms from falling into the containers while filling. For

FIG. 780



Apparatus for sterilizing solutions by passing them through a Berkefeld-type filter. A–Tube over filter candle. B–Filter candle. C–Rubber tube connection. D–Air filter. E–Vacuum gauge.

FIG. 781



Apparatus for filtering sterile solutions. A–Filling needle. B–Glass protecting bell. C–Two-way stopcock. D–Air filter.

filling ampuls a large hypodermic needle or capillary glass tube is attached to the glass tube under the bell by means of a short piece of rubber tubing treated as previously described (see page 1792).

A rubber atomizer bulb is attached to the air filter and the apparatus is now ready to use. By turning the stopcock to the proper position the liquid is made to rise in the burette by pressure on the atomizer bulb. By giving the stopcock a half turn the solution will then flow out of the burette into the sterile containers. To the top of the burette is attached an air filter to prevent contamination as air flows in to replace the liquid flowing out.

Before using, the filling attachment is carefully wrapped in gauze and sterilized in an autoclave.

This apparatus can be easily assembled, readily cleaned, and sterilized.

The solution can be received in a large sterile container and the receiver is connected with the filling device by means of but one connection. The possibility of contamination is therefore reduced to a minimum. The expense of the apparatus is low and the speed with which ampuls may be filled is, of course, dependent upon the skill of the operator.

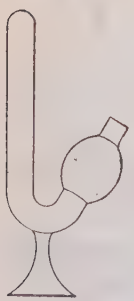
Sterilizing Ampuls—The method to be followed in sterilizing the empty glass ampuls has already been given. Delicate glass apparatus, used in filling ampuls, must be sterilized with great care, especially avoiding sudden changes of temperature. It must be heated and cooled slowly, whether sterilized in an autoclave or with dry heat. It is not possible to outline specific directions for sterilizing the solutions to be filled into ampuls, as they must be given individual consideration. Some substances are not injured by even the heat of the dry air sterilizer, while others are destroyed by 100° C. (212° F.) and therefore must be pasteurized. Often the alkalinity of the glass used for making ampuls is a contributing factor in decomposition. Substances, reported sensitive to heat, may often be successfully sterilized at the higher temperatures if contained in non-soluble glass when, under the influence of alkalies from soluble glass, they would have been quickly destroyed.

When ampuls have been filled and sealed for the final sterilization, if the autoclave temperature and pressure are permissible, that is always preferred and may be easily secured for the pharmacist by heating the sealed ampuls for fifteen minutes in a concentrated solution of calcium chloride to 121° C. (249.8° F.), thus providing the usual autoclave conditions within the ampuls.

The filled, sealed, and sterilized ampuls, may be tested for imperfect sealing and small fractures by warming in a dilute methylene blue solution. The air in the imperfect ampul is forced out on warming and as they cool, the blue solution is sucked into the ampul and the imperfect ampuls readily detected.

In cases of low temperature sterilization, or of solutions which are especially difficult to sterilize, or for extemporaneous dispensing, an antiseptic agent, such as cresol (0.1 to 0.4 per cent), or phenol (0.3 to 1.0 per cent), or other suitable germicide may be added to insure sterility.

Fig. 782



Fermentation tube

When a germ-proof filter is employed the heat-sterilization process may be omitted provided the filter has been tested, and proved to be free from leakage or defects, and to be actually germ-proof, and the operation conducted under aseptic conditions.

Sterility Testing—After the final sterilization of the ampuls, especially those solutions which are sterilized by pasteurization or filtration, they should be tested for sterility by "planting" a portion of the solution from several ampuls in a culture medium. This should consist of broth to which salt and peptones have been added. Prepare a culture medium as described on page 1576, under Lactose, Litmus, Agar-agar, omitting the agar, and adjusting to a slight alkaline reaction.

This solution is filled into fermentation tubes, see Fig. 782, and sterilized by the discontinuous method. One or two cc. of the solution to be tested should be added to each tube and they should be incubated at body temperature (37½° C.) for seven days. Control tubes containing the broth, but none of the solution being tested, should also be incubated at the same time.

At the end of seven days, the solution in the tubes containing the "plants" should be perfectly clear, should show no signs of gas in the closed end of

the tube, and in every way should be identical with the liquid in the control tubes.

The U. S. P. X requires the following solutions to be sterilized.

AQUA DESTILLATA STERILISATA. U. S. Sterilized Distilled Water

[Aq. Dest. Steril.]

Water, freshly distilled, a sufficient quantity.

Place freshly distilled water, neutral to litmus paper, in sterilized containers of insoluble glass, having a capacity of not over 1000 cc. each. Stopper the containers with plugs of purified absorbent cotton, wrapped in gauze. Fasten stout, non-absorbent paper or tinfoil over the top of the plug and the lip of the flask, and sterilize in an autoclave, under steam pressure giving a temperature of 115° C., for thirty minutes.

If an autoclave is not available, close the mouth of the flask containing the freshly distilled water with a plug of purified absorbent cotton wrapped in gauze, boil the contents actively for one hour and allow the water to cool without removing the cotton plug. Until ready for use, protect the mouth of the flask and the plug from infection through dust by wrapping the top of the flask tightly with paper.

Sterilized Distilled Water should be used within twenty-four hours after its distillation if it is to be employed for intravenous injection. For other uses, it is preferable that the Water be resterilized after each opening and that it be used within a month after its preparation.

It is necessary to carry out the details of this process with great exactness, if the product is to be satisfactory. Freshly distilled water is directed because water is likely to contain many microörganisms even a few hours after distillation and these, even if afterwards destroyed in the sterilization process, render the water unfit for use as they consist of foreign protein and practically make a "bacterin" of the water, which if injected intravenously, may cause notable systemic disturbance.

A "hard" or so-called "non-soluble" glass flask is directed, as the ordinary glass flask is slightly soluble in boiling water and would partially dissolve. Under these conditions the sterilized water, when cold, would contain numerous crystals of silicates and the water could not be used as a solvent for hypodermic or intravenous injections.

N. F. Preparations—Ampullæ; Liquor Procainæ Hydrochloridi.

LIQUOR SODII CHLORIDI PHYSIOLOGICUS. U. S. Physiological Solution of Sodium Chloride

[Liq. Sod. Chlor. Physio.—Physiological Salt Solution, Normal Salt Solution]

	Metric	Alternative
Sodium Chloride	8.5 Gm.	124 gr.
Distilled Water, a sufficient quantity,		
To make	1000 cc.	2 pints

Dissolve the sodium chloride in sufficient freshly distilled water, neutral to litmus paper, to measure 1000 cc., and filter, returning the filtrate until free from foreign particles. Transfer the solution to a sterile flask of insoluble glass, having a capacity of about 1000 cc., and stopper with a plug of purified absorbent cotton, wrapped in gauze. Fasten stout, non-absorbent paper or tin foil over the top of the plug and the lip of the container, and sterilize in an autoclave under steam pressure maintaining a temperature of 115° C., for thirty minutes.

This solution should be used within twenty-four hours if it is to be employed for intravenous injection. For other uses it is preferable that the solution be resterilized after each opening, and that it be used within a month after its preparation.

This preparation must be made with great caution, observing the directions exactly, since it is frequently used for intravenous or subcutaneous injection and also in surgical operations, and its sterility is important. The water is required to be freshly distilled, since distilled water, even after standing for a few days, is likely to be contaminated with microörganisms and, although these are destroyed by the process of sterilization, the toxins remain and cause disturbances when injected. A hard glass flask should also be used or the solution will contain soluble silicates which may separate in needle-like crystals on cooling.

The N. F. V has listed the following sterile solutions under the heading *Ampulla* (ampuls):

AMPULLÆ CAFFEINÆ SODIO-BENZOATIS. N. F. Ampuls of Caffeine Sodio-Benzoate

[Ampul. Caff. Sod.-Benz.]

A sterile aqueous solution of caffeine sodio-benzoate containing 0.25 Gm. in each cc.

	Metric	Alternative
Caffeine Sodio-Benzoate	**55 Gm.**	1 oz. av. 411 gr.
Sterilized Distilled Water, a sufficient quantity To make	**220 cc.**	7 fl. oz. 210 min.
To fill about	**100 ampuls**	

Dissolve the caffeine sodio-benzoate in sufficient sterilized distilled water to make 220 cc. [7 fl. oz. 210 min.] of solution and filter. Fill into ampuls and sterilize at 60° C.

NOTE—0.1 per cent of cresol or 0.25 per cent of phenol may be added to this solution for extemporaneous preparation.

Average dose—1 ampul.

AMPULLÆ CAMPHORÆ. N.F. Ampuls of Camphor

A sterile solution of camphor in cottonseed oil containing 0.2 Gm. of camphor in each cc.

	Metric	Alternative
Camphor	**22.0 Gm.**	340 gr.
Cottonseed Oil, containing not more than 1 per cent of free fatty acid, a sufficient quantity, To make	**110 cc.**	3 fl. oz. 345 min.
To fill about	**100 ampuls**	

Sterilize about 110 cc. [3 fl. oz. 345 min.] of the cottonseed oil by heating to 120° C., for one hour in a suitable flask, and cool to or below 60° C. Dissolve the camphor in sufficient of this sterilized oil to make 110 cc. [3 fl. oz. 345 min.] of solution, and filter. Fill into double-end ampuls and sterilize by heat at 100° C.

Average dose—1 ampul.

AMPULLÆ EMETINÆ HYDROCHLORIDI. N. F. Ampuls of Emetine Hydrochloride

[Ampul. Emet. Hydrochl.]

A sterile solution of emetine hydrochloride in physiological salt solution containing 0.03 Gm. in each cc.

	Metric	Alternative
Emetine Hydrochloride	**3.3 Gm.**	51 gr.
Physiological Solution of Sodium Chloride, a sufficient quantity, To make	**110 cc.**	3 fl. oz. 345 min.
To fill about	**100 ampuls**	

Dissolve the emetine hydrochloride in sufficient physiological salt solution to make 110 cc. [3 fl. oz. 345 min.] of solution. Titrate 5 cc. of the solution with tenth-normal potassium hydroxide, using phenolphthalein as indicator, and adjust by the addition of normal hydrochloric acid or of sodium bicarbonate so that each cubic centimeter of solution will show 0.01 per cent of free hydrochloric acid. Filter, fill into ampuls, and sterilize by heat at 100° C.

Average dose—1 ampul.

AMPULLÆ IODI. N. F. Ampuls of Iodine

[Ampul. Iodi—IODINE SWABS]

	Metric	Alternative
Iodine	**35 Gm.**	1 oz. av. 74 gr.
Potassium Iodide	**25 Gm.**	365 gr.
Distilled Water	**300 cc.**	9 fl. oz. 288 min.
Alcohol, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Dissolve the potassium iodide in the distilled water, add the iodine and about 650 cc. [22 fl. oz.] of alcohol. Agitate the mixture until the iodine is completely dissolved, then add sufficient alcohol to make the product measure 1000 cc. [2 pints].

Fill the liquid into ampuls of any desired size.

When dispensed with a pledget of absorbent cotton or gauze, for convenient application of the iodine solution to the skin, these are known as Iodine Swabs.

AMPULLÆ QUININÆ ET UREÆ HYDROCHLORIDI. N. F. Ampuls of Quinine and Urea Hydrochloride

[Ampul. Quin. et Urea Hydrochl.]

A sterile aqueous solution of quinine and urea hydrochloride containing 0.5 Gm. in each cc.

	Metric	Alternative
Quinine and Urea Hydrochloride	**55 Gm.**	1 oz. av. 411 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**110 cc.**	3 fl. oz. 345 min.
To fill about	**100 ampuls**	

Dissolve the quinine and urea hydrochloride in sufficient sterilized distilled water to make 110 cc. [3 fl. oz. 345 min.] of solution and filter. Fill into ampuls and sterilize by heat at 60° C.

Average dose—1 ampul.

AMPULLÆ QUININÆ DIHYDROCHLORIDI. N. F. Ampuls of Quinine Dihydrochloride

[Ampul. Quin. Dihydrochl.]

A sterile aqueous solution of quinine dihydrochloride containing 0.5 Gm. in each cc.

	Metric	Alternative
Quinine Dihydrochloride	**55 Gm.**	1 oz. av. 411 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**110 cc.**	3 fl. oz. 345 min.
To fill about	**100 ampuls**	

Dissolve the quinine dihydrochloride in sufficient sterilized distilled water to make 110 cc. [3 fl. oz. 345 min.] of solution. Titrate 1 cc. of this solution with tenth-normal potassium hydroxide solution, using phenolphthalein as indicator, and adjust the remaining solution by the addition of hydrochloric acid or of sodium bicarbonate so that each cubic centimeter will require 12.6 cc. of tenth-normal potassium hydroxide solution to produce a pink color with phenolphthalein. Then filter, fill into ampuls, and sterilize by heat at 100° C.

Average dose—1 ampul.

AMPULLÆ SODII CACODYLATIS. N. F. Ampuls of Sodium Cacodylate [Ampul. Sod. Cacodyl.]

A sterile aqueous solution of sodium cacodylate containing 0.3 Gm. in each cc.

	Metric	Alternative
Sodium Cacodylate	**33 Gm.**	1 oz. av. 72 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**110 cc.**	3 fl. oz. 345 min.
To fill about	**100 ampuls**	

Dissolve the sodium cacodylate in sufficient sterilized distilled water to make 110 cc. [3 fl. oz. 345 min.] of solution. To 5 cc. of this solution add 0.5 cc. of phenolphthalein T.S. and note the reaction. Then add to the solution if needed, sufficient hydrochloric acid or sodium carbonate to produce a slight pink, but not a deep color in the above test. Filter the solution, fill into ampuls and sterilize by heat at 100° C.

NOTE—For extemporaneous preparation 0.1 per cent of cresol or 0.25 per cent of phenol may be added to this solution.

Average dose—1 ampul.

Unofficial Sterile Solutions

In addition to the sterile solutions listed officially in the U. S. P. X and the N. F. V there are a large number of commercial preparations which, though they are unofficial have an extensive sale, and formulas for some of these are supplied with Type Processes for their preparation.

Type Process A—*General directions for preparing sterile solutions of substances which may be sterilized in an autoclave.*

Dissolve the salt or salts in sterilized distilled water (see page 1795), or in physiological solution of sodium chloride (see page 1795) in a flask of hard glass, making up to the exact volume specified. Filter the solution through a hard, Whatman filter (No. 50 preferred), in a Buchner funnel, using a vacuum pump (see pages 206 and 207) to hasten filtration, and filtering into a flask or bottle of hard glass. Return the filtrate if necessary until free from all foreign particles. Fill the solution into sterile containers of hard glass, *under aseptic conditions*, and immediately seal. Finally sterilize the filled and sealed containers by heating them in an autoclave at 15 pounds' pressure (121° C.) for twenty minutes. (See sterilization by steam under pressure, page 1783.)

Type Process B—*General directions for preparing sterile solutions of substances which may be sterilized at 100° C. in an Arnold sterilizer.*

Proceed exactly as directed under "A", (see above) except in the sterilization, where the filled and sealed containers are to be sterilized in an Arnold sterilizer, for one hour after the temperature has reached 100° C. (See sterilization by moist heat at 100° C. (212° F.) page 1782.)

Type Process C—*General directions for preparing sterile solutions of substances to be rendered sterile without the use of heat but by filtration through a Berkefeld-type filter.*

Dissolve the salt or salts in sterilized distilled water (see page 1795), or in physiological solution of sodium chloride (see page 1795), as directed, in a flask of hard glass, making up the exact volume specified. Filter the solution through a Berkefeld-type filter (see page 1787), which has been sterilized by boiling for one hour, or in an autoclave, and collect the solution in a sterile bottle or flask of hard glass. It is desirable to use a vacuum pump to facilitate filtration (see pages 206 and 207). Fill the solution into sterile containers, *under aseptic conditions*, and immediately seal. (See sterilization by filtration, page 1785.)

STERILE SOLUTION OF ATROPINE SULPHATE

A sterile solution of atropine sulphate in physiological salt solution containing 0.00065 Gm. ($\frac{1}{100}$ grain) in each cc.

	Metric	Alternative
Atropine Sulphate	**0.065 Gm.**	1 gr.
Physiological Solution of Sodium Chloride, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution, and adjust to a slight acid reaction, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF CALCIUM CACODYLATE

A sterile aqueous solution of calcium cacodylate containing 0.05 Gm. ($\frac{3}{4}$ grain) in each cc.

	Metric	Alternative
Calcium Cacodylate	**5 Gm.**	77 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF CALCIUM CHLORIDE

A sterile aqueous solution of calcium chloride containing 0.05 Gm. (¾ grain) in each cc.

	Metric	Alternative
Calcium Chloride	**25 Gm.**	365 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**500 cc.**	1 pint

Prepare a solution, filter, sterilize, and fill into 5 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—5 cc.

STERILE SOLUTION OF DEXTROSE (GLUCOSE)

(50 per cent Solution)

A sterile aqueous solution of dextrose containing 0.5 Gm. (7¾ grains) in each cc.

	Metric	Alternative
Dextrose, anhydrous	**500 Gm.**	16 oz. av. 300 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Prepare a solution, heating carefully, filter, sterilize, and fill into 50 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—50 cc.

STERILE SOLUTION OF HEXAMETHYLENAMINE

A sterile aqueous solution of hexamethylenamine containing 0.3 Gm. (4⅝ grains) in each cc.

	Metric	Alternative
Hexamethylenamine	**150 Gm.**	5 oz. av.
Sterilized Distilled Water, a sufficient quantity,		
To make	**500 cc.**	1 pint

Prepare a solution, filter, sterilize, and fill into 5 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—5 cc.

STERILE SOLUTION OF INDIGO CARMINE

(1 per cent Solution)

A sterile aqueous solution of indigo carmine containing 0.01 Gm. (⅙ grain) in each cc.

	Metric	Alternative
Indigo Carmine	**5 Gm.**	73 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**500 cc.**	1 pint

Prepare a solution, filter, sterilize, and fill into 1 cc. and 5 cc., sterile containers as directed under Type Process B, page 1798.

STERILE SOLUTION OF IRON ARSENITE (SOLUBLE)

A sterile aqueous solution of iron arsenite and ammonium citrate containing 0.065 Gm. (1 grain) in each cc.

	Metric	Alternative
Iron Arsenite and Ammoninm Citrate	**6.5 Gm.**	100 gr.
Quinine and Urea Hydrochloride	**1.0 Gm.**	15½ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution by dissolving the iron arsenite and ammonium citrate and the quinine and urea hydrochloride separately and then pouring the solution of quinine and urea hydrochloride into the solution of iron arsenite and ammonium citrate while stirring rapidly. Neutralize carefully with ammonia water using litmus paper, leaving the solution slightly acid, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process B, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF IRON CACODYLATE

A sterile aqueous solution of iron cacodylate containing 0.032 Gm. (½ grain) in each cc.

	Metric	Alternative
Iron Cacodylate	**3.2 Gm.**	50 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution by adding the salt to boiling water and immediately cooling, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—1 cc.

To prepare a sterile solution for intravenous injection, each cc. containing 0.013 Gm. ($\frac{1}{5}$ grain) of iron cacodylate, use 6.5 Gm. for 500 cc. of solution, filter, sterilize and fill into 5 cc., sterile containers by Type Process A, as directed on page 1798.

Average dose—5 cc.

NOTE—Some lots of iron cacodylate, while differing imperceptibly from others, so far as can be determined chemically, cause extreme irritation at the site of injection and also violent reactions. Each lot of salt should therefore be tested for irritation by injecting 0.2 cc. of a solution prepared as directed above into the arm of the operator. If more than a slight burning sensation is experienced, the salt should be rejected.

STERILE SOLUTION OF IRON CITRATE

A sterile aqueous solution of iron and ammonium citrate containing 0.065 Gm. (1 grain) in each cc.

	Metric	Alternative
Iron and Ammonium Citrate	**6.5 Gm.**	100 gr.
Quinine and Urea Hydrochloride	**1 Gm.**	15½ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution by dissolving the iron and ammonium citrate and the quinine and urea hydrochloride separately and then pouring the solution of quinine and urea hydrochloride into the solution of iron and ammonium citrate while stirring rapidly. Neutralize carefully with ammonia water, using litmus paper, leaving a slightly acid reaction. Filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process B, page 1798.

Average dose—1 cc.

NOTE—To prepare a sterile solution, each cc. containing 0.050 Gm. (¾ grain) of iron and ammonium citrate, use 5 Gm. of iron and ammonium citrate and 1 Gm. of quinine and urea hydrochloride for 100 cc. of solution. Filter, sterilize, and fill into 1 cc., sterile containers as directed above.

Average dose—1 cc.

STERILE SOLUTION OF MAGNESIUM SULPHATE

A sterile aqueous solution of magnesium sulphate containing 0.5 Gm. (7¾ grain) in each cc.

	Metric	Alternative
Magnesium Sulphate	**100 Gm.**	3 oz. av. 231 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**200 cc.**	6 fl. oz. 366 min.

Prepare a solution, filter, sterilize, and fill into 2 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—2 cc.

STERILE SOLUTION OF MERCURY CACODYLATE

A sterile aqueous solution of mercury cacodylate containing 0.032 Gm. (½ grain) in each cc.

	Metric	Alternative
Mercury Cacodylate	**3.2 Gm.**	50 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF MERCURY CYANIDE

A sterile solution of mercury cyanide in physiological salt solution containing 0.0013 Gm. ($\frac{1}{50}$ grain) in each cc.

	Metric	Alternative
Mercury Cyanide	**0.13 Gm.**	2 gr.
Physiological Solution of Sodium Chloride, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process B, page 1798.

Average dose—1 cc.

NOTE—To prepare a sterile solution, each cc. containing 0.005 Gm. ($\frac{1}{200}$ grain), use 0.5 Gm. of mercury cyanide for 100 cc. of solution. Filter, sterilize, and fill into 1 cc., sterile containers as directed above.

Average dose—1 cc.

STERILE SOLUTION OF MERCURY OXYCYANIDE

A sterile aqueous solution of mercury oxycyanide containing 0.0016 Gm. ($\frac{1}{625}$ grain) in each cc.

	Metric	Alternative
Mercury Oxycyanide	**0.8 Gm.**	11⅔ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**500 cc.**	1 pint

Prepare a solution, filter, sterilize, and fill into 5 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—5 cc.

STERILE SOLUTION OF MERCURY SALICYLATE

A sterile suspension of mercury salicylate containing 0.130 Gm. (2 grains) in each cc.

	Metric	Alternative
Mercury Salicylate	13 Gm.	200 gr.
Guaiacol	2 cc.	32 min.
Oil of Theobroma, a sufficient quantity,		
To make	100 cc.	3 fl. oz. 183 min.

Prepare a uniformly smooth mixture by triturating the ingredients in a warm glass mortar, sterilize for one hour in an Arnold sterilizer, and fill into 1 cc., sterile containers, under aseptic conditions, while warm, using a large sterile glass syringe, and shaking the mixture thoroughly just before filling each container.

Average dose—1 cc.

STERILE SOLUTION OF MERCURY SUCCINIMIDE

A sterile aqueous solution of mercury succinimide containing 0.010 Gm. (⅙ grain) in each cc.

	Metric	Alternative
Mercury Succinimide	1 Gm.	15½ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	100 cc.	3 fl. oz. 183 min.

Prepare a solution, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF PROCAINE HYDROCHLORIDE

A sterile aqueous solution of procaine hydrochloride containing 0.02 Gm. (⅓ grain) in each cc.

	Metric	Alternative
Procaine Hydrochloride	2 Gm.	31 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	100 cc.	3 fl. oz. 183 min.

Prepare a solution, filter, sterilize, and fill into 1 cc. sterile containers as directed under Type Process A, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF RED MERCURIC IODIDE (BINIODIDE)

A sterile aqueous solution of mercury iodide containing 0.01 Gm. (⅙ grain) in each cc.

	Metric	Alternative
Mercuric Iodide, Red	1 Gm.	15½ gr.
Sodium Iodide	1 Gm.	15½ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	100 cc.	3 fl. oz. 183 min.

Prepare a solution, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF SILVER NITRATE

A sterile aqueous solution of silver nitrate containing 0.01 Gm. (⅙ grain) in each cc.

	Metric	Alternative
Silver Nitrate	1 Gm.	15½ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	100 cc.	3 fl. oz. 183 min.

Prepare a solution, neutralize, if necessary, with tenth-normal sodium hydroxide, and fill into 1 cc., dark-colored sterile containers, as directed under Type Process B, page 1798, except that the solution need not be sterilized. After finishing, the container should be kept in a carton as the solution is darkened by exposure to light.

STERILE SOLUTION OF SODIUM ARSENATE

A sterile aqueous solution of sodium arsenate containing 0.00026 Gm. ($\frac{1}{250}$ grain) in each cc.

	Metric	Alternative
Sodium Arsenate	0.065 Gm.	1 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	250 cc.	8 fl. oz. 218 min.

Prepare a solution, filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process B, page 1798.

Average dose—1 cc.

STERILE SOLUTION OF SODIUM BICARBONATE

A sterile aqueous solution of sodium bicarbonate containing 0.050 Gm. (¾ grain) in each cc.

	Metric	Alternative
Sodium Bicarbonate	**50 Gm.**	1 oz. av. 293 min.
Sterilized Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Prepare a solution, filter, sterilize, and fill into 20 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—20 cc.

STERILE SOLUTION OF SODIUM CHLORIDE (CONCENTRATED)

A sterile aqueous solution of sodium chloride containing 0.085 Gm. ($1\frac{3}{10}$ grains) in each cc.

	Metric	Alternative
Sodium Chloride	**85 Gm.**	2 oz. av. 366 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Prepare a solution, filter, sterilize, and fill into 50 cc., sterile containers as directed under Type Process A, page 1798.

NOTE—50 cc. with 450 cc. of sterilized distilled water makes physiological solution of sodium chloride (normal salt solution).

STERILE SOLUTION OF SODIUM CITRATE
(For blood transfusion)

A sterile solution of sodium citrate in physiological solution of sodium chloride containing 0.01 Gm. (⅙ grain) in each cc.

	Metric	Alternative
Sodium Citrate	**10 Gm.**	146 gr.
Physiological Solution of Sodium Chloride, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Prepare a solution, filter, sterilize, and fill into 50 cc., sterile containers as directed under Type Process B, page 1798.

STERILE SOLUTION OF SODIUM IODIDE

A sterile aqueous solution of sodium iodide containing 0.1 Gm. (1½ grains) in each cc.

	Metric	Alternative
Sodium Iodide	**100 Gm.**	3 oz. av. 148 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Prepare a solution, add a small crystal of sodium thiosulphate, and adjust to a slightly alkaline reaction with normal sodium hydroxide. Filter, sterilize, and fill into 20 cc., sterile containers as directed under Type Process B, page 1798.

Average dose—20 cc.

STERILE SOLUTION OF SODIUM SALICYLATE

A sterile aqueous solution of sodium salicylate containing 0.2 Gm. (3 grains) in each cc.

	Metric	Alternative
Salicylic Acid, finest reagent grade	**43.13 Gm.**	1 oz. av. 192 gr.
Sodium Bicarbonate, finest reagent grade	**26.25 Gm.**	383 gr.
Sodium Citrate	**5 Gm.**	73 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**250 cc.**	8 fl. oz.

Dissolve the acid, sodium bicarbonate, and sodium citrate in 150 cc. of distilled water, in a flask of hard glass, with the aid of heat. Neutralize the solution carefully, using either sodium hydroxide solution or citric acid solution as may be required, and add sterilized distilled water to make exactly 250 cc. If preferred, and if obtainable, dissolve 50 Gm. of sodium salicylate, *free from phenol derivatives*, in sterilized distilled water to make 250 cc.

Filter, sterilize, and fill into 5 cc., sterile containers as directed under Type Process B, page 1798.

Average dose—5 cc.

STERILE SOLUTION OF SODIUM SALICYLATE AND SODIUM IODIDE WITH COLCHICINE

A sterile aqueous solution containing sodium salicylate 0.050 Gm. (¾ grain), sodium iodide 0.050 Gm. (¾ grain), and colchicine 0.000032 Gm. ($\frac{1}{2000}$ grain), in each cc.

	Metric	Alternative
Sodium Salicylate, free from phenol derivatives	**50 Gm.**	1 oz. av. 293 gr.
Sodium Iodide	**50 Gm.**	1 oz. av. 293 gr.
Colchicine	**0.032 Gm.**	½ gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**1000 cc**	2 pints

Prepare a solution, adding a small crystal of sodium thiosulphate, and adjust to a slightly alkaline reaction, with normal sodium hydroxide. Filter, sterilize, and fill into 20 cc., sterile containers as directed under Type Process B, page 1798.

If sodium salicylate, free from phenol derivatives is unobtainable, it may be replaced in this formula by using salicylic acid (finest reagent grade) 43.13 Gm. (1 oz. av. 192 gr.), sodium bicarbonate (finest reagent grade) 26.25 Gm. (405 grains), and sodium citrate 5 Gm. (77 grains).

Average dose—20 cc.

STERILE SOLUTION OF SODIUM THIOSULPHATE

A sterile aqueous solution of sodium thiosulphate containing 0.1 Gm. (1½ grains) in each cc.

	Metric	Alternative
Sodium Thiosulphate	**100 Gm.**	3 oz. av. 148 gr.
Sterilized Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Prepare a solution, filter, sterilize, and fill into 10 cc., sterile containers as directed under Type Process C, page 1798.

Average dose—10 cc.

NOTE—To prepare a sterile solution, each cc. containing 0.5 Gm. (7¾ grains) of sodium thiosulphate, use 100 Gm. for 200 cc. of solution. Filter, sterilize, and fill into 2 cc., sterile containers as directed above.

STERILE SOLUTION OF STRYCHNINE SULPHATE

A sterile solution of strychnine sulphate in physiological salt solution containing 0.001 Gm. ($\frac{1}{65}$ grain) in each cc.

	Metric	Alternative
Strychnine Sulphate	**0.1 Gm.**	1½ gr.
Physiological Solution of Sodium Chloride, a sufficient quantity,		
To make	**100 cc.**	3 fl. oz. 183 min.

Prepare a solution, and adjust to a slightly acid reaction. Filter, sterilize, and fill into 1 cc., sterile containers as directed under Type Process A, page 1798.

Average dose—1 cc.

TYPICAL PRESCRIPTIONS

The following prescriptions are reproduced with several purposes in view: First, they place before the pharmacy student a rather comprehensive collection of modern prescriptions of many types, with which there should be familiarity. Secondly, they offer a basis for practice in prescription filling (see Part XVI) although it is strongly recommended that they be supplemented by prescriptions taken from the current files of drug stores in the vicinity of the college.

Thirdly, the prescriptions here given may suggest forms for prescribing approved therapeutic agents and may incidentally come to the attention of physicians. It is entirely within the province of the pharmacist, who has been able to develop the correct professional relationship with the physicians of his community, that he should at times suggest prescription forms. This opportunity may present itself during a friendly conversation or in a letter to physicians, or perhaps in a joint meeting of physicians and pharmacists. A publication of the American Medical Association, "The Pharmacopœia and the Physician", by Hatcher and Wilbert, and "Practical Materia Medica and Prescription Writing", by Oscar W. Bethea, which give typical prescriptions for various needs, are of special value in this connection.

Most of the prescriptions which follow were taken from the recent files of pharmacies in Philadelphia, Washington, and Detroit. They do not necessarily represent especially difficult prescriptions but rather the usual types received daily in a pharmacy. In a few instances, suggestions for filling have been added but in most cases the dispenser is given liberty to use his own knowledge of the physical or chemical characteristics of the several ingredients and their influence within the mixture, and then to proceed as his judgment suggests, a condition which pertains at the prescription counter of the pharmacy. These prescriptions are numbered in sequence, starting with a number of five figures. This large number has been used to give better training in dispensing, in the writing of labels and checking of figures.

32001

℞ For Mary Pierce

Hydrarg. Chlor. Corr.	gr.i
Fldext. Staphisag.	f℥i
Alcohol.	f℥i
Aq. Ros. q.s. ad	f℥iii

Misce.

Sig.—Poison—Apply as a wash.

White.

32002

℞ For Frank Rhodes

Sod. Salicyl.	℥iii
Aq. Ammon.	min.x
Liq. Ferr. et Ammon. Acet. q.s.	f℥iii

M.

Sig.—f℥i in water t.i.d.

Harris.

32003

℞ For M. R. Morgan

Pot. Chlorat.	℥ss
Acid. Hydrochl.	gtt.x
Tr. Ferr. Chlor.	gtt.lxxx
Tr. Aconit.	gtt.xii
Glycerin.	f℥ss
Aq. Font. q.s.	f℥ii

M.

Sig.—f℥i every three hours.

Britton.

Note—Introduce the powdered potassium chlorate into a clean, dry bottle. Add the hydrochloric acid, permit the reaction to continue for a few moments, add the tincture of ferric chloride, and the other ingredients; chlorine is developed, and some is dissolved.

32004

℞ For Baby Jones
Sol. Cupr. Sulph. (1 per cent) f℥iv
M.
Sig.—Use locally in mouth three times a day.
Reilly.

32005

℞ For Thos. J. Harris
Quin. Sulph. gr. lxxv
Acid. Hydrochl. Dil. min. lxxv

Smith.

Note—Dissolve the mild silver protein in the smallest possible quantity of water. Incorporate this syrupy liquid with the grated cacao butter and form suppositories by compression.

CHAPTER CXIII

MEDICINAL FOODS

The N. N. R. recognizes certain manufactured food products which are helpful in the treatment of special diseases. The professional pharmacist should be familiar with the conditions under which these are used and should be prepared to supply representative types when called for by the physician. The following descriptions and lists are taken in abstract from the N. N. R. (1925).

Medicinal foods are preparations of alimentary substances designed to supply special needs in the nutrition of the sick. The estimations of the nutritive values of these medicinal foods are here based on the calorific values of their carbohydrate, fat, and protein contents, and do not include the calorific values of any alcohol or glycerin that they may contain. In these computations the following factors are used as the equivalents in large calories of 1 Gm. of foodstuff: for carbohydrate, 4.1; for fat, 9.2; for protein, 4.1. The protein content of these foods has generally been estimated by multiplying the nitrogen content by 6.25. It is not, however, conceded that all of the nitrogen represents nutritional nitrogenous matter. They may be divided into the following classes; liquid mixed foods, protein foods, carbohydrate foods, and diabetic foods.

PROTEIN FOODS

Dry protein, predigested or not, may be used to increase the protein content of soups, gruels and other liquid foods. The predigestion of protein may be of value in conditions in which the digestive power of the stomach is lacking. In such cases meat fiber fails of digestion and may be irritating to the intestine. Predigested protein is also of value for use in rectal alimentation.

Dose—The dosage of dry protein is determined by the tolerance of the patient and by his nutritive needs. Each gram of dry protein yields about 4.1 calories.

The dry proteins are presented in the following principal forms: meat, predigested and in the form of a dry powder; casein, usually rendered more soluble by partial conversion to sodium caseinate; legumes, such as flour made from the soy bean; mixtures containing dry protein mixed with carbohydrate or other nutrients.

Calcium Caseinate, N. N. R.—*Calcii Caseinas*—Casein from cow's milk rendered partially soluble by combination with calcium, and containing not less than 1.4 per cent nor more than 2.1 per cent of calcium.

Uses—The diarrheal diseases of infancy are now generally treated by dietetic measures. A useful food may be made from the curd of milk (casein) and diluted milk, the resultant mixture containing a moderate amount of fat, a small amount of sugar and a large amount of protein (casein) and salts, particularly salts of calcium. To obtain such a food a mixture of calcium caseinate and diluted milk is used.

Dose—For infants and children, calcium caseinate is administered in a mixture of milk and water or milk and gruel, approximately ½ oz. (10 Gm.) being used, 1 pint (500 cc.) of solution, and the mixture boiled. For adults, it may be mixed with milk, skimmed milk or buttermilk in the proportions of ⅔ oz. (20 Gm.) to 1 quart (1000 cc.) of diluent.

Calcium caseinate is a yellowish-white, fluffy powder, free from "sour" or rancid odor, and having a characteristic, slightly saline taste; permanent in the air.

On agitation with warm water, calcium caseinate partially dissolves, forming a pseudo-solution or turbid suspension; insoluble in alcohol, ether or chloroform.

Casec—A brand of calcium caseinate manufactured by Mead Johnson and Company.

Larosan-Roche—*Stoeltzner's Casein Calcium*—A brand of calcium caseinate, containing 1.75 per cent of calcium, manufactured by F. Hoffmann-LaRoche and Company.

Protolac—A brand of calcium caseinate manufactured by the Dry Milk Company.

Casein, N. N. R.—*Caseina*—The protein separated from milk by the action of acids or enzymes and purified. It contains not less than 15 per cent of nitrogen, calculated on the moisture-free material.

Uses—Casein is used as a food, being added to other ingredients of the diet when it is desired to increase the content of protein in the diet. This occurs occasionally in the feeding of infants, in the nutrition of adult convalescents, and undernourished persons, and in the dietotherapy of diabetes. Casein is readily digested, furnishes phosphorus in addition to the usual amino-acid derivatives of proteins, and represents a protein of good nutritional quality. Casein is also used in the preparation of special foods for diabetics or others for whom a regimen poor in carbohydrate or fat may be desired.

Dose—The quantities which may be desirable to use vary widely in accord with the purpose of the feeding. Hence the dosage cannot be designated in definite terms.

Casein is soluble in ammonia water and in aqueous solutions of the fixed alkali hydroxides; insoluble in water, alcohol, ether, chloroform, or benzene. A suspension of casein in water slightly reddens blue litmus paper, but casein has both acidic and basic properties.

Dry Peptonoids, N. N. R.—A medicinal food prepared from beef, milk and wheat, containing 40 per cent of protein and 51.5 per cent of carbohydrate.

Uses—See general article, Dry Protein Foods. The nutritive value of 500 Gm. of dry peptonoids corresponds approximately to 1876 calories, of which 820 are produced by protein and 1056 by carbohydrate. The largest dose usually given (16 Gm.) is, therefore, equivalent to about 60 calories.

Dose—For an adult, from ¼ to ½ ounce (8 to 16 Gm.), taken in water, milk, wine, broths, soups, etc.; also in gruels, in which case it should first be dissolved in a small quantity of water.

Manufactured by the Arlington Chemical Company.

CARBOHYDRATE FOODS

Prepared carbohydrate foods are used mostly in infant feeding. They are made by the action of amylolytic enzymes on starch or by other modes of conversion by which the starch is changed into dextrin, maltose or glucose. The calorific value of these foods is determined on the assumption that 1 Gm. of the dry carbohydrate is equivalent to 4.1 calories.

Dextrose, U. S. P.—(See page 895).

Borcherdt's Malt Sugar, N. N. R.—A mixture containing approximately: maltose 87.40 per cent; dextrin 4.35 per cent; protein 4.40 per cent; ash 1.90 per cent, and moisture 1.95 per cent.

Uses—Borcherdt's malt sugar may be used where maltose is indicated in the feeding of infants, particularly in the treatment of constipation. The nutritive value of 500 Gm. of Borcherdt's malt sugar corresponds to approximately 1985 calories.

Dose—It may be used in all milk mixtures in the same proportions as lactose (sugar of milk), that is, 1 ounce (30 cc.) of Borcherdt's malt sugar (2 tablespoonfuls) to a 20 ounce mixture.

Manufactured by Borcherdt Malt Extract Company.

It is a pale brownish-yellow powder having a malt odor and a sweet taste. It is somewhat hygroscopic and soluble in water.

Dextri-Maltose No. 1, Mead's, N. N. R.—A mixture of maltose, 51 per cent; dextrin, 42 per cent; sodium chloride, 2 per cent and moisture 5 per cent.

Dextri-Maltose No. 2, Mead's, N. N. R.—A mixture of maltose, 52 per cent; dextrin 43 per cent; and moisture 5 per cent.

Dextri-Maltose No. 3, Mead's, N. N. R.—A mixture containing: maltose, 51 per cent; dextrin 41 per cent; potassium bicarbonate, 3 per cent, and moisture, 5 per cent.

It is a pale yellowish-white, granular, odorless powder, having a faintly sweetish taste. It is somewhat deliquescent on exposure to the air. It is soluble in water.

Uses—On the claim that maltose is more readily assimilable than other forms of sugar, Mead's dextri-maltose is proposed to supplement the carbohydrate of cow's milk.

Extract of Malt, U. S. P.—(See page 462).

Borcherdt's Malt Extract (Plain), N. N. R.—A preparation essentially similar to extract of malt, U. S. P., but containing 10 per cent. of glycerin.

Manufactured by Borcherdt Malt Extract Company.

Borcherdt's Malt, Cod Liver Oil and Iron Iodide—Each 100 cc. contains ferrous iodide 0.88 Gm. (4 grains per fluidounce), cod liver oil, 25 cc. and Borcherdt's malt extract (plain), 75 cc.

Borcherdt's Malt Cod Liver Oil and Phosphorus—Each 100 cc. contains phosphorus, 0.009 Gm. (1/6 grain per fluidounce), cod liver oil, 25 cc. and Borcherdt's malt extract (plain), 75 cc.

Dose—From 8 to 15 cc. (2 to 4 fluidrachms), three times a day, after meals.

Borcherdt's Malt Extract with Cascara Sagrada—Each 100 cc. represents cascara sagrada 12.5 Gm. (60 grains per fluidounce) in Borcherdt's malt extract (plain).

Borcherdt's Malt Extract with Cod Liver Oil—Each 100 cc. contains cod liver oil, 25 cc., and Borcherdt's malt extract (plain), 75 cc.

Borcherdt's Malt Extract with Creosote—Each 100 cc. contains creosote, U. S. P., 0.83 cc. (4 minims per fluidounce) in Borcherdt's malt extract (plain).

Borcherdt's Malt Soup Extract—A mixture obtained by adding potassium carbonate 1.1 Gm. to each hundred grams of malt extract, according to the formula of Dr. Keller, Universitäts-Kinderklinik, Breslau, Germany.

Malt Extract (Unmedicated)-P. D. and Co., N. N. R.—A preparation essentially similar to extract of malt, U. S. P., but containing 10 per cent of glycerin.

Manufactured by Parke, Davis & Company.

Malt Extract with Cod Liver Oil—P. D. and Company—Each 100 cc. contains Norwegian cod liver oil, 25 cc. and malt extract (unmedicated)-P. D. and Company, 75 cc. with chocolate and extract of vanilla as flavoring agents.

Maltine, N. N. R.—A preparation essentially equivalent to extract of malt, U. S. P., but containing 3.88 per cent of alcohol.

Manufactured by The Maltine Company.

Maltine with Cascara Sagrada—Each hundred cubic centimeters represents cascara sagrada 12.5 Gm. (60 grains per fluidounce) in maltine as a vehicle.

Maltine with Cod Liver Oil—Maltine, 70 per cent and cod liver oil, 30 per cent.

Maltine with Creosote—Each hundred cubic centimeters represents creosote, U. S. P., 0.83 cc. (4 minims per fluidounce) in maltine as a vehicle.

Maltine Ferrated—Each hundred cubic centimeters represents iron pyrophosphate, 1.65 Gm. (8 grains per fluidounce) in maltine as a vehicle.

Maltine Malt Soup Extract—Maltine containing potassium carbonate 1.1 Gm. in each hundred grams according to the formula of Dr. Keller, Universitäts-Kinderklinik, Breslau, Germany.

Malto-Yerbine—A liquid containing in each hundred cubic centimeters an extract of 6.6 Gm. (30 grains per fluidounce) of eriodictyon (yerba santa), also flavoring composed of the essential oils of anise, cassia, coriander and caraway in maltine as a vehicle.

Borcherdt's Dri-Malt Soup Extract, N. N. R.—Each one hundred grams contains: maltose, 71.1 Gm.; dextrin, 13.5 Gm.; protein, 8.7 Gm.; salts, 2.9 Gm., and moisture, 3.8 Gm. The nutritive value of 500 Gm. of Borcherdt's dri-malt soup extract corresponds approximately to 1812 calories, of which 1734 calories are yielded by carbohydrate.

Uses—Borcherdt's dri-malt soup extract is intended for use in preparing the malt soup of Dr. Keller, Universitäts-Kinderklinik, Breslau, Germany.

Borcherdt's Dri-Malt Soup Extract with Wheat Flour—A powder obtained by evaporating to dryness by a special process a mixture of 100 Gm. of malt soup extract and 50 Gm. of wheat flour.

Uses—Borcherdt's dri-malt soup extract with wheat flour is designed for use in preparing the malt soup of Dr. Keller, Universitäts-Kinderklinik, Breslau, Germany.

Manufactured by Borcherdt Malt Extract Company.

Loeflund's Malt Soup Stock, N. N. R.—A preparation essentially similar to extract of malt U. S. P., but containing a small amount of potassium carbonate. It contains in 100 Gm.: maltose, 54.26 Gm.; dextrin, 17.60 Gm.; protein, 3.73 Gm.; inorganic salts, 2.11 Gm., and water, 22.30 Gm.

Actions and Uses—Loeflund's malt soup stock is designed for use in preparing the malt soup of Dr. Keller, Universitäts-Kinderklinik, Breslau, Germany.

Distributed by Britt, Loeffler and Weil.

Mead's Dry Malt Soup Stock, N. N. R.—A mixture containing in 100 Gm.: maltose, 23.5 per cent; dextrin, 23.5 per cent; wheat flour, 46.5 per cent; potassium bicarbonate, 1.5 per cent, and moisture, 5 per cent.

Uses—Mead's dry malt soup stock is designed for use in preparing the malt soup of Dr. Keller, Universitäts-Kinderklinik, Breslau, Germany.

Manufactured by Mead, Johnson and Company.

Lacto-Dextrin, N. N. R.—A mixture composed of lactose, 73 per cent; dextrin, 25 per cent; and desiccated lemon juice 2 per cent.

Uses—The administration of lacto-dextrin is proposed as a means of promoting the growth of the normally present aciduric organisms, B. acidophilus and B. bifidus in the alimentary tract so as to make them the predominating organisms.

Dose—From 50 to 120 Gm. (2 to 4 ounces) dissolved in four times its bulk of hot water, three times a day preferably half an hour or an hour before meals. The nutritive value of 500 Gm. of lacto-dextrin corresponds approximately to 1900 calories.

Manufactured by the Battle Creek Food Company.

MODIFIED MILK PRODUCTS

Albumin Milk-Hoos, N. N. R.—*Dry Protein Milk*—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 Gm. contains, approximately, protein, 30 Gm.; butter fat, 25 Gm.; lactose (milk sugar), 15 Gm.; ash, 4 Gm., and small amounts of free lactic acid.

Uses—When suitably mixed with water, albumin milk-Hoos is said to be useful for correcting intestinal disorders of infants and children.

Dose—For the majority of conditions, albumin milk-Hoos should be administered in small quantities according to age and condition of the patient, after a period of starvation of from twelve to forty-eight hours. Suitable carbohydrates may gradually be added to the preparation as indicated by the clinical conditions.

Louis Hoos, distributor.

Mead's Powdered Protein Milk, N. N. R.—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 Gm. contains approximately protein 37 Gm., fat 31 Gm. (beef tallow 15 Gm., cocoanut oil 15 Gm., cod liver oil 1 Gm.), free lactic acid 3 Gm., lactose 19 Gm., and ash 4.6 Gm.

Uses—When suitably mixed with water, powdered protein milk is said to be useful for correcting intestinal disorders of infants and children.

Uses and Dose—The same as for Albumin Milk.

Powdered Protein Milk-Merrell-Soule, N. N. R.—*Dry Protein Milk*—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 Gm. contains approximately protein, 38 Gm.; butter fat, 27 Gm.; free lactic acid, 3 Gm.; lactose, 24 Gm., and ash, 5 Gm.

Uses and Dose—The same as for Albumin Milk.

Manufactured by the Merrell-Soule Company.

FOODS FOR DIABETICS

The essential purpose of dietetic treatment of diabetes is to abolish glycosuria, hyperglycemia and acidosis by the reduction of the carbohydrate intake. Foods containing not more than 10 per cent of sugar-forming carbohydrate have generally been regarded as permissible; those containing higher amounts must be used with greater caution. It is therefore necessary that the carbohydrate content of foods for diabetics should be accurately stated. There is no foundation for the claims that special forms of starch, such as oatmeal, toasted bread, or certain proprietary preparations, are any better assimilated than other kinds of starch.

The place of carbohydrates other than glucose and starch, *e.g.*, levulose, inulin, lactose (milk), is not quite so thoroughly investigated, but it is safe to conclude that their superior assimilability is apparent rather than real. They may sometimes be useful for special purposes in the hands of specialists; but, in general, they should be reckoned with as are the ordinary forms of carbohydrate.

Since in diabetes it is the carbohydrate metabolism which is first and most profoundly altered, it is necessary to know the percentage of utilizable carbohydrate in every food that the patient eats. In all except the milder forms of diabetes, it is also essential to know the quantities of protein and fat, as well as the amount of carbohydrate. It is therefore particularly necessary to know the carbohydrate content of every food used in the treatment of diabetes, and only somewhat less important to know their contents of protein and fat.

It has long been known that sugar can be formed from protein and consequently the protein of the diet must be carefully restricted in quantity; but this requirement has been widely ignored by practitioners. Since the diabetic foods which are low in carbohydrate are generally correspondingly high in protein, they cannot be given to the patients in unrestricted amounts.

Another requirement more recently emphasized is the restriction of fat and the total calorific value of the diet. Often diminution of fat is more important than decrease of carbohydrate as a means of combating acidosis. Foods for diabetics are generally concentrated foods, formerly prized on account of their high food value, but now sharply restricted on this very account. Diabetics should not be treated by the use of mere lists of permissible and forbidden foods; the total diet should be exactly prescribed in carbohydrate, protein, fat, and total calories in accordance with the ability of the individual patient to digest these foods. The chief function of a diabetic bread is to provide a palatable, breadlike vehicle for butter, cheese or the like. A high food value is not important or even desirable. The less utilizable carbohydrate such articles contain, the more general may be their use. A high protein content limits the use of such articles in severer cases, since in such cases the tolerance for protein must be considered as well as that for carbohydrate. Uniformity of composition from month to month, reliable analytical data, a maximum of surface for a minimum of carbohydrate and protein, palatability, low price and availability are points of chief interest in appraising

usefulness of such articles. For the purpose of avoiding too high a ration, bulky substances of low nutritive value are useful in the diet. Such are green vegetables and bran; and such use of cellulose or other indigestible material for the purpose of making up a sufficiently bulky and satisfying diet is largely replacing the former employment of concentrated foods for diabetics. Foods classed in this list contain, as a rule, not more than approximately 10 per cent of the nutriment in the form of utilizable sugar-forming carbohydrates.

Cellu Flour, N. N. R.—*Cellulose Flour-C. F. M.*—Commercially pure cellulose in the form of flour.

Uses—Cellu flour is used as a means of filling out reduced diets as in the Allen treatment for diabetics. It is a non-nutritive food substitute used to give bulk to foods, thus serving to satisfy hunger without furnishing nourishment. Purified and bleached wood pulp, straw pulp or cotton fiber is further treated to facilitate grinding to flour.

Cellu flour is white to grayish white in color; odorless and tasteless.

Dose—Cellu flour, after admixture with bran, baking powder, eggs, "India gum", or liquid petrolatum in varying proportions may be used for the preparation of imitation bread, muffins, cookies, griddle cakes, pie crust, etc. These preparations may be seasoned with salt, spices or saccharin.

Manufactured by The Chicago Dietetic Supply House.

Diaprotein Prepared Casein Flour, N. N. R.—Casein to which has been added 4 per cent of a leavening mixture composed of sodium bicarbonate, monocalcium phosphate and sodium aluminum sulphate.

Uses—This flour is employed in cases such as diabetes, in which carbohydrate is contraindicated.

Dose—Diaprotein prepared casein flour is adapted for the preparation of bread, cake, muffins, biscuits, etc.

Manufactured by The Diaprotein Company.

Gluten Food A, Barker's, N. N. R.—A gluten flour prepared from wheat, containing not more than 4 per cent of carbohydrate and 87 per cent of protein.

It is a granular powder, practically without odor or taste. It is insoluble in water.

Uses—Barker's gluten food A is indicated when a diet practically free from carbohydrate is desired, especially in severe forms of diabetes. It can be taken uncooked or made into muffins.

The nutritive value of 500 Gm. of Barker's gluten food A corresponds approximately to 1845 calories, of which 1785 are yielded by protein, 80 by carbohydrate and 30 by fat.

Manufactured by Herman Barker.

Gluten Food B, Barker's, N. N. R.—A gluten flour prepared from wheat, containing not more than 7 per cent of carbohydrate and 85 per cent of protein.

It is a granular powder, practically without odor or taste. It is insoluble in water.

Uses—Barker's gluten food B is indicated when a diet relatively free from carbohydrate is desired. It may be used uncooked or made into muffins.

The nutritive value of 500 Gm. of Barker's gluten food B corresponds approximately to 1917 calories, of which 1742 are yielded by protein, 145 by carbohydrate and 30 by fat.

Manufactured by Herman Barker.

Gluten Food C, Barker's, N. N. R.—A gluten flour prepared from wheat, containing not more than 12 per cent of carbohydrate and 83 per cent of protein.

It is a granular powder, practically without odor or taste. It is insoluble in water.

Uses—Barker's gluten food C is indicated when a diet relatively free from carbohydrate is desired. It can be taken uncooked or made into muffins.

The nutritive value of 500 Gm. of Barker's gluten food C corresponds approximately to 1970 calories, of which 1700 are yielded by protein, 240 by carbohydrate and 30 by fat.

Manufactured by Herman Barker.

Hepco Flour, N. N. R.—A flour prepared from the soy bean, having approximately the following composition: protein, 42.9; carbohydrate, 22.4, of which less than one-half readily yields sugar; fat, 20.8; ash, 5.1; fiber, 4.2, and water, 4.6.

Uses—It is claimed that clinical trials have shown that the carbohydrate in hepco flour is, in the main, not sugar producing and that therefore hepco flour is a suitable food material in cases in which carbohydrate is contraindicated, as diabetes and amylaceous dyspepsia. It has also been suggested for use in the diet in obesity. The nutritive value of 500 Gm. of this flour corresponds approximately to 2,300 calories, of which 880 are yielded by protein, 460 by carbohydrate (on the assumption that all the carbohydrate is utilized), and 960 by fat.

Manufactured by Waukasha Health Products Company.

Hoyt's Gluten Special Flour, N. N. R.—A gluten flour containing protein, 80 per cent, fat, 1 per cent and starch, less than 5 per cent.

Uses—Hoyt's gluten special flour may be given when a diet relatively free from carbohydrate is desired, especially in diabetes. It does not make a satisfactory bread, but may be used to prepare muffins, flat cakes or gruel.

The nutritive value of 500 Gm. of Hoyt's gluten special flour corresponds approximately to 1810 calories, of which 1640 are yielded by protein, 45 by fat, and 125 by carbohydrate.

Manufactured by the Pure Gluten Food Company.

Intarvin, N. N. R.—An artificial fat made from fatty acids having an odd number of carbon atoms. Intarvin is composed of the glyceryl ester of margaric acid admixed with small quantities of glyceryl esters of pentadecylic, palmitic and stearic acids, 82 per cent; liquid petrolatum, 12 per cent; water, 6 per cent.

Uses—Intarvin is proposed for use in diabetes mellitus on the ground that fatty acids containing an odd number of carbon atoms do not yield ketone bodies on oxidation in the normal or diabetic organism, and that for this reason it may with advantage replace the natural fats in the diet.

Dose—From the total number of calories required for the day, the number supplied by the diet is deducted; the remainder is the number of calories per day to be furnished by intarvin. The caloric value of intarvin is 8 calories per gram—approximately 120 calories per heaping tablespoonful.

Intarvin is best taken in its natural granulated form, followed by a drink of water, tea or coffee. It may also be taken mixed with other food, such as salads, coffee, sweet cream or tomatoes.

Lister's Prepared Casein Diabetic Flour, N. N. R.—Milk casein to which has been added a leavening mixture consisting of sodium bicarbonate and acid calcium phosphate and also some sodium chloride, and saccharine 0.057 Gm. per one hundred grams.

Uses—This flour is employed in conditions in which carbohydrate is contraindicated, such as diabetes.

The nutritive value of 500 Gm. of Lister's prepared casein diabetic flour corresponds approximately to 1900 calories of which 1735 are yielded by protein and 165 by fat.

Dose—Lister's prepared casein diabetic flour is adapted for the preparation of muffins, biscuits, cookies, cakes, etc.

Manufactured by Lister Bros., Inc.

Nutrivoid Flour, N. N. R.—A vegetable product composed chiefly of unassimilable carbohydrates (mannans). It contains fat, 0.92 per cent; protein, 4.31 per cent; non-utilizable carbohydrate, 85.37 per cent.

Uses—Nutrivoid flour is used as a means of filling out restricted diets as in the Allen treatment of diabetes. It is a non-nutritive food substance, used to give bulk to food, thus serving to satisfy hunger without furnishing nourishment. Being unassimilated, it adds roughage to the diet and thus aids peristalsis.

Dose—Nutrivoid flour, after admixture with bran and baking powder, eggs, "India gum" or liquid petrolatum in varying proportions, may be used for the preparation of imitation bread, muffins, cookies, griddle cakes, pie crusts, etc. These preparations may be seasoned with salt, spices or saccharin.

Manufactured by the Nutrivoid Diabetic Flour Company.

Soy Bean Gruel Flour, N. N. R.—A flour prepared from the soy bean, having approximately the following composition: protein, 44; fat, 20; sucrose, 10; ash, 4.3; fiber, 2, and water, 4.6.

Uses—Soy bean gruel flour may be used for preparing muffins. It is indicated in cases in which a diet relatively free from carbohydrate is desired, as in diabetes and amylaceous dyspepsia. It has also been suggested for use in the diet in obesity. The nutritive value of 500 Gm. of this flour corresponds approximately to 2027 calories, of which 902 are yielded by protein, 205 by carbohydrate, and 920 by fat.

Manufactured by Cereo Company.

MEAT EXTRACTS

Extracts of meat, as originally sold, were obtained by boiling lean beef in water, skimming off the separated fat, filtering from the coagulated protein and concentrating to a paste. The industry developed through a mistaken notion as to the exact nature of the nitrogenous bodies which went into solution, and before the days of clear ideas on protein chemistry.

In principle, the process of manufacture is still the same; but the "extract" is now largely a by-product. Much of it is obtained by boiling down the thin liquid resulting from the cooking of meat in the canning processes, the same water being used for a number of batches of meat. In the stockyards industries, the trimmings and waste too small for the canning process are often converted into extract. Frequently, hearts, livers, lungs, brains and, indeed, anything which will yield an extract are boiled up for the purpose, giving a product of variable composition.

Roughly speaking, these extracts contain about 20 per cent of water, 20 per cent of inorganic salts, and 60 per cent of organic matter. The average results obtained from a considerable number of analyses of American products are represented by these figures:

Water	20 per cent
Inorganic salts	22.5 per cent
Gelatin and albumose	16.5 per cent
Flesh bases	26.4 per cent
N-free extractives	14.6 per cent

As the figures indicate, the food value of the extracts is rather low, and entirely disproportionate to the high prices at which they are sold. The high selling price is excused by the prevalence of the old notion, carefully fostered, that about 30 pounds of beef must be boiled down to obtain 1 pound of extract. The food value is measured by the albumose and gelatin derivatives present, and to some extent by the nitrogen-free extractives. The percentage amounts of these are often lower than those given above, while the creatin and similar derivatives are higher.

Meat extracts have some value on account of their flavor, in the preparation of soups and bouillons. They are condiments, rather than foods. To use them as foods, in place of meat, as was attempted in the early days of their manufacture, is perhaps even dangerous because of the content of inorganic salts, especially potassium salts. The classification of these products as foods should be discouraged, but their use as appetizers or condiments in the preparation of foods for the sick may still be admitted.

MEAT JUICES

Meat juices proper are obtained by warming chopped meat to a temperature short of the coagulating point of the muscle proteins present (not above 55° C.) and forcing out the juice by means of strong pressure. These juices as usually made, with or without the addition of water, are intended for immediate consumption. It is difficult to prepare them in a stable form for later use, for their sterilization and filtration eliminate most of the protein. Preservation has also been attempted by the addition of considerable quantities of salt, glycerin or alcohol, all of which are objectionable.

Most, if not all, commercial "meat juices" are apparently made by very different methods from the foregoing. In place of being actual protein solutions they are suspensions of blood, finely divided meat powder, peptone-like bodies and other animal derivatives, preserved by aid of glycerin, alcohol and salts. The name "meat juice" is incorrect when applied to such mixtures, whatever their nutritive value may be, and properly speaking, under this designation they are misbranded. It is possible to prepare mixtures of this description which possess considerable food value, but the method of preservation is of the utmost importance.

The essential value of meat juice lies in its food content, which consists, in the case of home-made cold process products, of a liberal percentage of soluble meat protein. The latter may be valuable as food but can scarcely be assumed to furnish any other *unique* therapeutic advantage.

The non-protein portion of the juice represented in beef extract may promote appetite and secretion and perhaps have some ill-defined or indefinable stimulating effect.

PART XII

CHAPTER CXIV

HOMEOPATHIC PHARMACY

HOMEOPATHY was founded by Dr. Samuel Hahnemann, a German physician, born in Meisen, Upper Saxony, on April 10th, 1755.

It was Hahnemann who formulated the system of therapeutics—*Similia similibus curantur*—"like cures like", which is the basis of homeopathic medicine. He first announced his system about 1796.

He made his first "provings" with cinchona, and later "proved" many remedies, such as arsenic, ipecac, belladonna, arnica, nux vomica, veratrum album, hyoscyamus, etc. Hahnemann gave explicit directions for the preparation of homeopathic remedies, and the fundamental rules for all his tinctures and dilutions are found in "Hahnemann's Materia Medica Pura".

His method of making tinctures from the fresh plants, was more complicated than the present homeopathic method; he originally made his tinctures according to a classification based upon the proportion of diluent or menstruum used, compared with a unit quantity of drug, as follows:

Class 1. Tinctures prepared with equal parts by weight of plant juice and alcohol.

Class 2. Tinctures expressed by the aid of two parts of alcohol added to three parts of plant tissue.

Class 3. Tinctures prepared with two parts by weight of alcohol to one part of plant tissue.

Class 4. Tinctures prepared with five parts by weight of alcohol added to one part of plant tissue.

Other numerical classes followed a similar principle of increasing the amount of alcohol in proportion to the amount of drug.

The present method is much simpler, and specifies 10 per cent drug strength for most of the remedies.

Essentials of Homeopathic Pharmacy—The pharmacy necessary in connection with homeopathy differs in many details from other and older methods. Although accuracy is the basis of every method, it is doubly important in homeopathic pharmacy, the distinctive feature of which is its simplicity. Drugs when prepared as medicines for homeopathic use, are never mixed or compounded, but to render them available for use, each, in its natural state is, after proper subdivision, added singly to some vehicle which will serve the purpose of a preservative, as well as a means of extension or dilution.

Cleanliness is of the utmost importance in preparing homeopathic remedies, and the most conscientious care is required in handling drugs of different kinds, and in keeping them from contact with each other. Care must be observed in storing to protect from vapors, odors and the dust from other substances and also in keeping them in cool, airy, dry, and darkened places.

Nomenclature—In the Homeopathic Pharmacopœia of the United States, Third Revision, 1914, issued by the American Institute of Homeopathy, the retention of older botanical names is due to the technical terminology used for

nearly a century, which, like the names of animals yielding medicinal substances, it was deemed unsafe to change. As a rule, the Latin titles as heretofore used in the literature of homeopathy are retained; the generic names of plants and animals are adopted as leading ones, excepting where usage has adhered to the specific name; *e.g.*, Chamomilla is retained in preference to the use of the present botanical genus name Matricaria. The species name, however, has been added in all cases.

The English derivations from Latin titles are also preferred, owing to long usage, such as Aconite instead of Monkshood. The English titles of the chemical salts accord with the latest approved rules of chemical nomenclature. The common English names, such as iron, gold, silver, and lead have been omitted, however, as it has been preferred to arrange them under Ferrum (ferric and ferrous), Aurum, Argentum, and Plumbum, respectively. The common synonyms of medical literature are retained, and the alkaloids and neutral proximate principles are not specially distinguished by Latin terminology. Instead of Strychnia or Strychnine, the homeopath writes *Strychninum*, and for Quinine the older form of *Chininum* is retained. The German nomenclature is used for a great many of the drugs. Thus Cinchona is called *China*; Worm Seed, "*Cina*"; Calomel, "*Mercurius dulcis*"; and Mercury, "*Mercurius vivus*"; Sodium bromide, "*Natrum Bromatum*", etc.

Drugs and Medicinal Substances—A brief definition of the subjects, according to the tenets of Homeopathy may be of interest.

Drugs are defined as substances which have the power of disturbing the health of the living organism. Each drug is capable of exerting this power in a manner peculiar to itself, and therein differs and may be distinguished from other drugs in their tests (provings) upon the normal organism.

The toxic or pathogenic property or power of drugs under certain conditions known to the physician, becomes a curative agent in disease. Hence, substances which are primarily toxic or pathogenic, are secondarily medicines when prescribed in disease, and prepared for that purpose by the pharmacist.

Derivation of Drugs—The drugs from which the materia medica is derived represents all great natural divisions, such as animal, plant, and mineral, and also many artificial products of chemistry. There are about six hundred and ninety official remedies in the Homeopathic Pharmacopœia, but of the thirty-two or more animal substances official, only a few are in common use.

Plants used as homeopathic medicines are much more numerous. Next to them in frequency of use come the chemical preparations, metals, and minerals. Animal substances should be prepared from perfect and healthy specimens and in their pure, unadulterated state, unmixed with any other substance. They should be protected against light, air, and moisture, if they are to be preserved before being made into tinctures or triturations.

With few exceptions, as nux vomica, ipecac, china and cina, the drugs are used and preparations made from them while fresh and undried. Every homeopathic pharmacist gathers many fresh drugs at the season when most active, and according to the rules laid down in the Homeopathic Pharmacopœia. Thus, if he is to collect whole plants, they are to be collected in the flowering season during sunny weather. They should be carefully cleaned by shaking, gentle rubbing, or brushing, without the contact of much water, or still better, only clean specimens are to be selected.

The Unit of Medicinal Strength—To avoid the varying strengths advised by Hahnemann for different drugs and to secure uniformity in strength (drug power) of all preparations and attenuations, thereby making dilutions and triturations of equal degree correspond in medicinal strength, the revision

committee has in all cases made the dry, crude drug, the unit taken as the basis for calculation.

It should be understood, however, that the freshly collected undried drugs are still required in the preparation of tinctures, and the plant moisture is to be regarded as a part of the vehicle or menstruum, it being evident that the water contained in the plant is but a solvent and forms no part of its medicinal substance.

Adopting this rule in the tincture-making processes, the rule of the British Homeopathic Pharmacopœia has been followed, thereby securing uniformity of strength.

In every instance, the dry, crude substance is taken as the starting point from which to calculate its strength, and with very few exceptions, the mother tinctures contain all of the soluble matter of one grain of the dry plant in ten minims of the tincture.

The tincture, therefore, represents ten per cent of medicinal substance, or, in other words, the soluble constituents of one-tenth of the amount of crude drug, represent the 1× (1/10) corresponding in strength with the 1× trituration. Uniformity is thus secured and the signs 1× or 1/10, in connection with any form of attenuation will always represent a drug power of one-tenth. The sign 2× will show the presence of 1/100 part drug substance, and 3× will show 1/1000 part.

Preparations of Drugs—General Principles—Starting with crude drugs, the next step is to prepare them for medicinal use. There are two fundamental forms, the fluid and the dry form, to be governed by the following directions and principle.

All substances soluble in the proper menstrua or vehicles may be made into solutions or tinctures and their dilutions, and also may be made into triturations with milk sugar, but insoluble or only partially soluble substances may only be made into triturations.

Aqueous solutions are made of substances which are soluble in water but not in alcohol, or, when soluble in alcohol, are subject to chemical change or decomposition. These are to be dissolved in the proportion of 1/10, 1/100, 1/1000, depending upon the degree of solubility of the substance. Aqueous solutions are, as a rule, unstable and will keep but a short time. They should be freshly made.

Solutions of fluids in alcohol: These are equivalent to tinctures, and are made of substances which yield either wholly or in part their medicinal properties to alcohol. This applies to liquids like turpentine, oils, etc. These should be made on the decimal scale; that is, in proportion of one part by weight of medicinal substance to be added to sufficient alcohol to make ten parts by volume, and hence equal to the first decimal dilution to be marked 1×. If not soluble in the proportion of one to ten, they should be prepared by adding one part, by weight, of drug to ninety-nine parts, by volume, of alcohol, and the product marked 2×. Such solutions are also to be made of alcohol of known strength in order that they may be employed in making the succeeding dilution.

If liquid acids or drugs contain water, this should also be deducted from that contained in the solvent and the anhydrous acid or drug taken as the unit of strength.

Homeopathic Tinctures

Tinctures are alcoholic solutions of solids or semi-solids. Most tinctures are made from plants or their parts and their treatment deserves special mention. It is very important that tinctures should be of uniform strength,

instead of varying greatly on account of the variability of water contained in the same plant at different seasons and under difficult conditions of growth.

Fresh, succulent plants and other substances containing water should be treated according to the fundamental rule, that the dry crude drug is taken as the starting point from whence to calculate the strength of the tincture. Hence the pharmacist is to proceed by first taking a suitable quantity of the fresh plant or substance containing water, weighing it, evaporating on a water bath until dry and thereby determining the percentage of water present in the fresh plant. Allowance must be now made for this in the preparation of the menstruum.

The dry sample of crude material is then taken as the unit of strength, the tincture being made to represent one part of this dry crude material in each ten parts of completed preparation. It is, however, understood that the fresh green plant is to be used in the preparation of the tincture.

Having determined the amount of dry substance obtainable from a given quantity of the fresh moist material, this is to be compared with the formula for this tincture in the Homeopathic Pharmacopœia. If the weight shows less moisture than permitted by the formula, add enough distilled water to the moist magma to equal the standard weight. If, on the contrary, the amount of moisture exceeds that permitted by the standard formula, deduct enough from that intended for the dilution of the solvent alcohol to reduce it to the standard weight. Or, when for practical reasons this cannot be done, resort to the slower method by cautious drying in moderate temperature, or evaporating enough of the drug moisture to reduce it to the standard of the formula.

In this process, both in the case of deficiency and of excess of water in the drug, it is to be remembered that the tincture finally consists of alcohol, the necessary proportion of water, plus that of the drug substance dissolved. The preparation of tinctures is then continued according to one of the following processes of maceration or percolation.

Maceration—This process is preferable in the treatment of large quantities of drug material needing ample time for the extraction of medicinal properties. If the drug substance can be finely sliced or reduced to pulp in a glazed mortar, this should be done, otherwise it may be used without cutting or crushing as directed under its special head in the Homeopathic Pharmacopœia.

Having ascertained the excess or deficiency of water, strictly according to the rule given above, place the material, reduced to magma, or in its natural state if unreducible, into a macerating jar or wide-mouthed bottle, and add the prescribed quantity of solvent, making it cover the whole mass if possible. The jar or bottle should be carefully stoppered or sealed to prevent evaporation, placed in a dark room of ordinary temperature, and shaken every day. The time necessary for the extraction and solution of the medicinal substance is variable, and it is safe to allow the process of maceration to continue from two to four weeks, according to the nature of the material. The clear liquid is then decanted, the residue transferred to a clean linen cloth or bag, pressed, and the liquids mixed.

Percolation—This process is rarely used in homeopathic pharmacy and the methods have been described in Chapter XXIII.

Dilutions or Liquid Attenuations—The homeopathic axiom calls for the utmost simplicity in prescribing and preparing drugs, as only one medicine is used at a time; that is, one medicine is never mixed with another medicine. It is a principle of Homeopathy that a very small quantity of medicine will produce effects, provided it is well diluted with menstruum or solvent, since it is

assumed that the immense increase in points of contact more than compensates for the minuteness of the quantity.

The process of dilution by a progressive scale of one part of tincture to one hundred parts of vehicle, known as the centesimal scale, was recommended by Hahnemann and adopted by him as the standard. Under this rule, each attenuation contains just 1/100 part as much of the drug substance as the preceding attenuation. In order to secure intermediate grades of strength, there has been introduced the method of diluting in the proportion of one in ten, in place of one in one hundred, thus constituting the decimal scale. The great advantage offered in the use of this scale has led to its almost universal acceptance and adoption for the preparation of dilutions and triturations.

Attenuation or extension is accomplished in the process of dilution, as well as in that of trituration, with lactose or sugar of milk, by the interposition of the vehicle between either the molecules of the fluid or the particles of the solid drug to be attenuated. This interposition is molecular in the case of soluble substances. In dry triturations there occur only the inter position of lactose between the minutest particles attainable by trituration of hard, insoluble substances.

In the decimal scale the original quantity of medicine is divided progressively by ten, so that the first decimal (1×) contains 1 to 10, the second decimal (2×), 1 to 100, the third decimal (3×) 1 to 1000 of the original substance which is suspended in, or attenuated, or expanded by the diluent which is usually alcohol or other menstruum. As solutions and tinctures according to the rules are to contain one part of drug substance in ten parts by volume of diluent, each tincture (with few exceptions) is equal in medicinal strength to the first decimal dilution (1 to 10 or 1×).

Where certain drugs are insoluble in the proportion of one to ten and require more solvent, like arsenicum album, phosphorus, sulphur, etc., their original solutions or tinctures, should be prepared in the proportion of one to one hundred, or one to one thousand, dependent on the degree of solubility, and the resulting solutions or tinctures are to be regarded as the second decimal (2×) or third decimal (3×), respectively.

To Make Dilutions or Attenuations of Soluble Substances—Take a new, well-cleaned vial, of a capacity of four drachms or more, measure into it 1 cc. of the tincture to be diluted, and, with a file, mark on the vial the height of the liquid. Then add 9 cc. of the alcohol and likewise mark the height of the whole on the vial; cork it well with a well-washed, flawless cork, and shake thoroughly until the contents are well mixed. Pour this dilution into another clean, well-corked vial and mark it with the name of the medicine, followed by the sign 2×, indicating the second decimal solution.

The first vial bearing the marks is now used as the measuring vial for subsequent dilutions. These are to be made in the same manner, by pouring 1 cc. of the preceding dilution into the measuring vial up to the lowest mark, giving at least ten forcible shakes for each attenuation, and then adding 9 cc. of alcohol to the highest mark, shaking, turning into another vial, labeling and marking it 3×, and so on as far as desired.

Dispensing alcohol of 87 per cent is used from the 3× upwards, unless otherwise directed in Part Two of the Homeopathic Pharmacopœia.

Belladonna ϕ 1/10	1 volume
Distilled Water	4 volumes
Dispensing Alcohol	5 volumes
Equal to	10 volumes

This produces Belladonna 1–100 or 2×.

If tinctures are not made in accordance with the formula of 1–10, and if their medicinal strength is known, the volume of the diluent will have to be calculated accordingly. If the tincture is made in proportion of 1–100, add 9 volumes of solvent to 1 part of the tincture, and mark the dilution 3×. If the tincture is in proportion of 1 to 1000, the first dilution made as above is to be marked 4×, etc.

Dilutions from Triturations—The first dilution prepared from a trituration is 8× and should be made by dissolving one grain of the 6× trituration in 50 minims of distilled water, and adding thereto 50 minims of dispensing alcohol. The next dilution (9×) should be made by adding to each minim of the 8× dilution 9 minims of dispensing alcohol, etc. Each attenuation should be shaken thoroughly at least ten times.

Homeopathic Triturations

Triturations consist of any medicinal substance triturated as intimately as possible with lactose. The method of Hahnemann is still adhered to with the exception of using one part of the drug to 9 parts—instead of 99 parts of lactose, and instead of adhering to the one-hour rule, the time to be allotted to triturations is determined by the nature of the substance triturated and by the fineness to which it is possible to reduce it. If an insoluble substance, this can best be determined by the microscopic test as will be shown. Mortars and pestles should be as clean as it is possible to make them by steam or by washing them with water and rinsing with alcohol, especially for non-volatile or insoluble substances like copper, lead, sulphur, etc.

First Trituration—Add 1 part by weight of the drug to 9 parts by weight of finely powdered lactose and triturate until the largest drug particles do not exceed 1–500 of an inch in diameter: This rule is inapplicable to moist and soluble substances and relates chiefly to those which are hard and practically insoluble, such as metals and minerals. Most of the metals require many hours of trituration before this degree of fineness is reached. The product is to be designated as the first decimal trituration, 1 in 10 (1×).

Second Trituration—This is made by adding 1 part by weight of the 1× trituration to 9 parts by weight of lactose, and by continuing the process of trituration until the largest drug particles have been reduced to no more than 1–2000 of an inch in diameter, except in case of drugs with which experiment has demonstrated the impossibility of attaining this degree of fineness.

The *Third, Fourth* and subsequent triturations are to be made in the same manner, that is, by grinding one part by weight of the preceding trituration with 9 parts by weight of lactose, until the largest particles of the third trituration do not exceed 1–4000 of an inch in diameter, with some few exceptions where experiment has demonstrated the impossibility of reaching this degree of fineness.

Tincture Triturations—These are prepared directly from strong tinctures, consequently they contain the soluble constituents only of the drugs and should therefore be clearly distinguished from triturations made to include the entire drug substance. They can be designated by adding a minus sign above the figure denoting strength; for example $1\bar{\times}$ indicating that this preparation contains less of drug material.

In making, add 10 cc. of strong tincture and 10 Gm. of lactose, mix carefully in a mortar, and cover with white paper until the moistened powder is nearly dry; then triturate gently until quite dry.

Forms of Vehicles for Prescriptions

These, like all other conditions of homeopathic pharmacy, should be governed by simplicity and usefulness to the physician and patient. For this purpose pharmacists have employed certain forms made of sucrose or cane sugar and lactose, or milk sugar. These may be used simply as medicated powders or as pellets (globules), tablets, cones, etc. These are made sufficiently small to serve as a convenient vehicle for dosage.

Trituration Tablets—This form may be also given to triturations themselves; and as these tablets are always of known weight, they serve the purpose of measuring the dose and save the physician trouble and time. This method of prescribing is very popular with the homeopathic physician.

Medications—Medicated powders are prepared by adding to each 10 Gm. of lactose, 1 cc. of the next lower than the desired strength of dilution, mixing the same in a mortar, and triturating until fully dry. The resulting powder will represent the degree of strength next above the dilution used in its preparation and should be so marked.

Medicated Globules also called *pellets* or *pilules*, are made of cane sugar. They are formed into small globular masses of different sizes, designated according to the diameter of ten globules measured in millimeters. They should be made of the purest materials, should be perfectly white and odorless and able to withstand all the tests prescribed for sucrose or cane sugar.

Globules are medicated by placing them in a vial, and adding the dilution in sufficient quantity and allowing them to stand a sufficient length of time to saturate them; any excess of liquid being poured off.

Medicated Cones, also called *disks*, are made of sucrose and rendered more absorbent with the addition of a small amount of egg albumen, which makes them light and porous. They are formed in hemispherical masses, and are designated according to size by the diameter of the base in millimeters. The common size (number six) should absorb about two drops of dispensing alcohol. They should be medicated by adding a sufficient quantity of the dilution to saturate them, pouring off the excess of the liquid.

Homeopathic Prescriptions

(1) The name of the medicine is to be plainly written, preferably in Latin or in one of the names in the Special Part Two of the Homeopathic Pharmacopœia.

(2) The form should next be stated as indicated in the examples given below, defining carefully by the signs in use whether a tincture, dilution, or trituration is desired. This is done by adding the abbreviation, "Tinct." or "ϕ", "dil.", "trit.", or, in case of either of the latter, to the number of the dilution or trituration the sign "×" or "c" (decimal or centesimal scale) as an exponent, "*e. g.*", "3×", "6×", "3c", etc.

(3) If the medicated, molded form is desired, this is also to be plainly stated in words, *e. g.*, tablets, pellets, etc.

(4) The quantity should also be stated explicitly in the usual signs of metric or apothecaries' weights.

(5) The dose and its frequency of repetition is plainly to be written under the head of Signa or Directions.

Abbreviations: Homeopathic prescriptions are often abbreviated, sometimes to an extreme, the nomenclature permitting this without ambiguity.

Example of Homeopathic Prescriptions:

℞ Bryonia ϕ gtt. xx
Aquæ dest. f ʒiv
Misce.
Signa: One teaspoonful every two hours.

℞ Belladonna ʒ x dil. min. xx
Aquæ dest. f ʒii
Misce.
Sig: One teaspoonful every hour.

℞ Nux vomica 6× 3 iv
on pills no. xxxv
Misce.
Signa: Take five pills every two hours.

℞ Chininum ars. 3× trit. ℥ i
Sacch. lact ℥ ii
M. ft. pulv. no. xxiv
Sig: One powder every two hours.

℞ Ferrum phos. 2× T. T. ʒii
Signa: One tablet every hour.

PART XIII

THE PHARMACIST IN COMMUNITY HEALTH SERVICE

CHAPTER CXV

HOUSEHOLD PESTS AND THEIR ELIMINATION

"A PRESENT help in trouble" might be the phrase which the general public applies to the pharmacist when annoyed by the several varieties of household pests. When the house fly arrives, the housewife no longer energetically wields the fly swatter, but hies herself to the drug store to ask for one of the several deadly preparations that may be used as a spray to kill flies. With the coming of March it is to the drug store that she goes to get naphthalene, camphor, or some other remedy for the exterminating of those fabric pests called moths. Or, it may be, that the pantry has suddenly been invaded by roaches or ants, or, upon moving into a new home the disgusted homemaker will discover that the house is inhabited by more than her family, perhaps by bedbugs or fleas. Under such circumstances her unfailing help is the pharmacist. So it may readily be seen that a knowledge of household pests, their life history, and a means of controlling and eradicating them is most necessary.

The demands from the public for methods of elimination have been so insistent that the United States Department of Agriculture and the United States Public Health Service have issued a number of Bulletins in which are set forth the life history of the several pests and the best known methods of control. Liberal quotations from these Bulletins are included in this Chapter by permission, and a bibliography is added.

In practically every instance the first step in destruction of these annoying pests is to find the breeding places and also the sources of food supply and to eliminate these. Other measures usually must follow but much of the difficulty is overcome when these two points have been taken care of.

Insects play a definite rôle in the transmission of disease. Many of the most serious ills of man are conveyed from person to person through the medium of mosquitoes, flies, lice, ticks, and other forms of vermin. How the transmission of disease is effected, the particular insects acting as carriers, and the means of combating such pests have all become matters with which the public is concerned.

Flies

Recently it has been possible to convict the fly of many of the crimes and misdemeanors of which it is guilty. We now know that flies, instead of being harmless insects, of moment only when they invade our food supplies, are in reality highly dangerous, and that a single fly may be responsible for the development of typhoid fever or other illness of a serious nature.

Kinds of Flies—There are many kinds of flies, not all of which have the same structure, habits, or methods of reproduction.

The varieties of interest in connection with public health are the house fly, the blue bottle or blow fly, the green bottle fly and the stable fly. Of these the house fly is the most important. This insect is ordinarily present in

all parts of the world and lives in practically any climate adapted to man. Nine-tenths of the flies found within or near dwellings belong to this group, although a number of other species so closely resemble house flies in appearance that differentiation may be impossible by other than experts. The favorite haunt of the house fly is the dwelling of man, and it is seldom found away from human habitations.

Reproduction—Flies are extremely prolific. The stages in the life cycle occupy at the most but a few days, and sexual maturity is reached within three or four days from the date of birth. As the eggs deposited by the female usually number a hundred or more, an enormous increase in the fly population is possible within a short period of time.

Nearly all flies breed in organic filth. A favorite medium is horse manure, but decaying vegetables, fermenting kitchen refuse, human excreta, and putrefying animal matter offer sites which are nearly as well adapted to the conditions necessary for propagation. The barn manure pile may be the place of origin of thousands of flies, the unprotected and unscreened privy serves as an excellent nidus for their growth, while fermenting foodstuffs and other waste food products scattered about the yard may also assist in their propagation.

The breeding season varies with the climate, usually beginning during May in the North, but more often in early April or March in the South; propagation continues until late September. The fly population is usually greatest during August and September, after which it very rapidly diminishes.

Carriers of Disease—Flies may transmit disease in either of two ways. The first method is by mechanical transference, whereby the insect becomes contaminated with the parasites or microörganisms of disease as a consequence of frequenting filth and places where these agents abound, thus carrying pathogenic organisms directly to food or drink partaken of by man. This is by far the most common method of conveyance.

The second method of disease transmission is by inoculation; that is, the actual injection into the system by the insect of pathogenic organisms or parasites.

Typhoid fever is the most common and important infection of man conveyed by flies.

Food purchased in fly-ridden markets may be a source of contamination, and if eaten uncooked may lead directly to illness. Cooked food of whatever nature may be contaminated subsequent to the cooking, constituting a serious menace to health. Irrespective, then, of the precautions we exercise as individuals, we are all more or less exposed to the infection of typhoid fever through common sources. Further, as a result of the laxity of others, even when we ourselves may have exercised every precaution necessary to prevent the development of flies, our lives are frequently endangered.

Eradicative Measures—The most successful method of ridding a community of flies is to institute a continued campaign for that purpose. It is only by the united efforts of all residents, supplemented by the support of the health department and civic organizations in general, that progress in fly eradication is possible.

How to Exclude and Destroy Flies—The principal effort to control this dangerous insect must be made at the source of supply—its breeding places. Absolute cleanliness and the removal or destruction of anything in which flies may breed are essential.

The Use of Screens—A careful screening of windows and doors during the summer months, with the supplementary use of sticky fly papers, is a protective measure against house flies known to everyone. As regards screening

it is only necessary here to emphasize the importance of keeping food supplies screened or otherwise covered so that flies can gain no access to them. This applies not only to homes, but also to stores, restaurants, milk shops, and the like.

Traps—The most common form of trap is the conical or cuboidal wire-gauze affair, baited with saccharine substances and arranged in such a manner that the insect passes through a small opening into a large space from which it is unable to emerge. As traps go, they are generally effective, but flies, like animals, are often reluctant to enter places from which they can not escape.

Poisons—Of substances poisonous to flies, formalin is perhaps most useful. It should be diluted with about 40 parts of water and placed in saucers about the room, at the same time removing all other liquids. After being denied all fluids for several hours the flies will drink the formalin solution and die, but the success of the plan is wholly dependent upon the complete removal of other liquids. A modification of this plan is to make the dilution with milk, placing a piece of bread in the saucer on which the flies may alight.

A fly poison about equal in efficiency to the formalin solution mentioned above can be prepared with sodium salicylate. A solution should be made by adding three teaspoonfuls of sodium salicylate (a powder) to a pint of water. As this solution is somewhat repellant to flies, three tablespoonfuls of brown sugar should be added.

A convenient container that will automatically keep the solution available for flies to drink may be easily made. A thin-walled drinking glass is half filled with the liquid poison. A saucer or small plate in which has been placed a piece of white blotting paper cut the size of the dish, is put bottom up over the glass. The whole is then quickly inverted, a match placed under the edge of the glass, and the container is ready for use. As the solution dries out of the saucer more liquid flows into the dish, always keeping the paper moist.

Of other fly poisons, mention should be made, merely for the purpose of condemnation, of those composed of arsenic. Fatal cases of the poisoning of children through the use of such compounds are far too frequent, and owing to the resemblance of arsenical poisoning to summer diarrhea and cholera infantum, it is believed that the cases reported do not by any means comprise the total. Arsenical fly-destroying devices must therefore be rated as extremely dangerous and should never be used, even if other measures are not at hand.

Sticky fly papers may serve a useful purpose.

Fumigation with sulphur dioxide gas, generated by burning ordinary brimstone, is a valuable insecticidal measure, but unfortunately is injurious to fabrics and to painted and other surfaces. The sulphur should be used in quantities not less than 1 pound per 1000 cubic feet of space, moistened with alcohol, and ignited, care being taken that the metal container is placed in a pan of water. Pyrethrum, or insect powder, may also be burned, but it is expensive and only temporarily stupefies the insects.

Fly Sprays—Probably the most efficient method so far developed for the destruction of flies about the home is the use of liquids sprayed about the room. Many of these have been offered within recent years. They consist of a special petroleum solvent, slightly lighter and less oily than kerosene, which has been percolated through from 5 to 10 per cent of good quality Dalmatian or Japanese insect powder. The percolate is subsequently perfumed with some odorous substance such as methyl salicylate. For spraying a tin pump-sprayer is used, the room should be closed for a short time, and sufficient liquid should be used to make the spray apparent throughout the room. These products are distinctly toxic to insects and one should be selected which will cause the death of the flies within a few moments.

Fly-swatting campaigns, of themselves, are not sufficient for the elimination of flies. Usually they are inaugurated only at the height of the fly season when a perceptible diminution in the number of insects present is not possible.

Mosquitoes

Mosquitoes are man's inveterate tormentors and foes. At the seaside, on the undrained prairies of the West and Northwest, in the far North, by woodland pool and mountain meadow, these bloodthirsty brigands in countless myriads waylay the individual on business or pleasure bent.

Swamps, ponds, and marshes, however, are not the only places which breed mosquitoes. A little rain water in an old tin can or undrained roof gutter if neglected will supply mosquitoes for a town or city neighborhood spreading discomfort, causing insomnia and tempting to profanity.

If mosquitoes were merely a bothersome plague there would be ample justification for unrelenting warfare against them; but when we consider that a certain kind of mosquito found in houses in the South will convey yellow fever from infected to healthy persons and that certain other kinds, by disseminating malaria, render many regions of great fertility almost uninhabitable, no argument for fighting them is necessary.

Protection from Bites—Spirit of camphor rubbed upon the face and hands or a few drops on the pillow at night will keep mosquitoes away for a time, and this is also a well-known property of oil of pennyroyal or oil of citronella. None of these substances is effective for more than a short time; that is to say, a single application will not last through the night. Oil of tar, oil of peppermint, lemon juice, and vinegar have all been recommended as mosquito repellents. An excellent mixture suggested by C. A. Nash, of New York, is as follows:

Oil of citronella	1 ounce
Spirit of camphor	1 ounce
Oil of cedar	½ ounce

Ordinarily a few drops on a bath towel hung over the head of the bed will keep the common house mosquitoes away. Where they are very abundant and persistent a few drops rubbed on the face and hands will suffice. Even this mixture, however, loses its efficiency toward the close of a long night. It is the habit of the yellow-fever mosquito (Stegomyia Aedes calopus Meig), to begin to bite at daylight. By that time the average person is sleeping very soundly, and the effects of the mixture will usually have passed largely away. It follows that in the Southern States, where this mosquito occurs, these protective mixtures are not supposed to be as effective as they are in the North. As a matter of fact, however, this last mixture, could it be applied shortly before dawn, would be as effective as under other circumstances.

A mixture recommended by E. C. Gane, of New York, is as follows:

Castor oil	1 ounce
Alcohol	1 ounce
Oil of lavender	1 ounce

This mixture was prepared for the purpose of avoiding the odor of the oil of citronella.

Oscar Samostz, of Austin, Texas, recommended the following formula:

Oil of citronella	1 ounce
Liquid petrolatum	4 ounces

This mixture greatly retards the evaporation of the oil of citronella.

Mr. B. A. Reynolds has used successfully in New Orleans 20 minims of oil of citronella to the ounce of petrolatum or lanolin.

A 5 per cent solution of potassium sulphate has been recommended, also oil of cassia. Pure kerosene has also been used extensively in the Philippines.

Screens and Canopies—Such obvious measures as the screening of houses, the use of netting for beds, and the wearing of veils and gloves after nightfall in badly infested regions need no detailed consideration. Screening of houses cannot be too carefully done, and adjustable, folding, or sliding window and door screens seem never to be tight; even with well-fitted screens there are often opportunities for mosquitoes to enter; constant care and vigilance alone will prevent this. In certain seasons in mosquito regions, mosquitoes will attempt to make their way through screens and are often able to do so. When the insects are very numerous, wire screens should be painted lightly with kerosene or oil of citronella.

With bed canopies there should be ample material to admit of a perfect folding of the canopy under the mattress, and the greatest care should be taken to keep the fabric well mended. It often happens in mosquito regions that little care is taken of the bed nettings in the poorer hotels, and it is necessary for perfect protection that a traveler in the Southern States should carry with him a pocket " housewife " and should carefully examine his bed netting every night, prepared to mend all tears and expanded meshes. Veils and nettings for camping in the Tropics or other regions where mosquitoes abound are absolutely necessary. Light frames are made to fit helmet-like over the head and are covered with mosquito netting. Similar frames, readily folded into a compact form, are made to form a bed covering at night, and every camping outfit for work in tropical or malarial regions should possess such framework and plenty of mosquito netting as an essential part of the outfit.

The size of the mesh in mosquito bars and window screens is important. Twenty meshes to the inch can be relied upon to keep mosquitoes out, but 15 to the inch admits some of them.

Smudges and Fumigants—Anything that will make a dense smoke will drive away mosquitoes, and various smudges are used by campers. For household use a number of different substances have been tried.

Pyrethrum Powders—Pyrethrum powders, known to the trade as Dalmatian insect powder, Persian insect powder and Buhach, are very effective when fresh and pure. Pyrethrum powders are usually used dry, and are puffed or blown into crevices frequented by insects, or puffed or blown into the air of a room in which there are mosquitoes. The burning of the powder in a room at night is common practice. The powder is heaped up in a little pyramid which is lighted at the top and burns slowly, giving it a dense and pungent smoke. Often the powder is moistened and molded roughly into small cones, and after drying it burns readily and perhaps with less waste than does the dry powder. Mosquitoes are stupefied by the smoke and fall to the floor, where they may be swept up and burned. With open windows and constant currents of fresh air this fumigation is not especially effective, and it is necessary, for protection, to sit in a cloud of smoke. The powder may be placed upon a metal screen above the chimney of a kerosene lamp, with the result that the vapor of the volatile oil will be dissipated. This is said to be very effective. It is economical in powder, and the odor is slight. Another method of burning the powder is to puff it from an insufflator into a burning gas jet. In New Orleans it has been found that in order thoroughly to clear houses of mosquitoes Pyrethrum must be burned at the rate of nearly 1 pound of powder to every 1000 cubic feet of space.

Mim's Culicide—This mixture is made of equal parts by weight of phenol or carbolic acid crystals and camphor. The phenol crystals are melted over a gentle heat and poured slowly over the camphor, resulting in the production of a clear, somewhat volatile liquid with an agreeable odor. This liquid is permanent, if kept in tightly closed containers. Volatilize 3 ounces of this mixture over a lamp of some kind for every 1000 cubic feet of space. A simple apparatus for doing this may be made from a section of stovepipe cut so as to have three legs and an outlet for draft, an alcohol lamp beneath and a flat-bottom basin on top. The substance is inflammable, but the vapor is not explosive. The vapor is not dangerous to human life except when very dense, but it produces a headache if too freely breathed. Rooms to be fumigated should be made as nearly air-tight as possible.

Sulphur Dioxide—Burning sulphur, in a small pot, at the rate of 2 pounds of sulphur for each 1000 cubic feet of space, is efficient against mosquitoes where fumigation in the case of possible disease-bearing mosquitoes is desired.

Catching Adult Mosquitoes—An interesting home-made apparatus in common use in many parts of the United States is very convenient and effective. It consists of a tin cup or a tin-can cover nailed to the end of a long stick in such a way that a spoonful or so of kerosene can be placed in the cup, which may then, by means of the stick, be pressed up to the ceiling so as to inclose one mosquito after another. When covered over in this way the captured mosquito will attempt to fly and be caught in the kerosene. By this method perhaps the majority of the mosquitoes in a bedroom—certainly all of those resting on the ceiling—can be caught before one retires.

Remedies for Mosquito Bites—The most satisfactory remedy seems to be moist soap. Wet the end of a piece of ordinary toilet soap and rub it gently on the puncture, and the irritation will soon pass away. Ammonia, alcohol, and glycerin, have also been recommended.

Abolition of Breeding Places—Stagnant water is necessary for breeding, and all possible places should be eliminated.

Where a rain-water tank is necessary it should be screened. The waste places in the immediate vicinity should be carefully searched for tin cans, bottles, and wooden or tin boxes in which water can accumulate and all such receptacles should be destroyed or carried away. The roof gutters of every building should be carefully examined to make sure that they are not clogged so as to allow the water to accumulate in pools. Where the branches of tall trees over-hang roofs this is especially likely to occur by the agency of falling leaves or twigs. The chicken pans in the poultry yard, the water in the troughs for domestic animals, the water cup of the grindstone are all places in which these mosquitoes will breed and water should not be allowed to stand in them for more than a day or so at a time.

Even in the house mosquitoes breed in many places where they may be overlooked. Where the water in flower vases is not frequently changed, mosquitoes will breed. They will breed in water pitchers in unused guest rooms. They will breed in the tanks in the water-closets in pipes and under stationary washstands where these are not frequently in use, and they will issue from the sewer traps in back yards of city houses during dry spells in the summer time when the sewers have not recently been flushed by heavy rains. In warehouses and on docks they breed abundantly in the fire buckets and in water barrels. Of course such places as these cannot be abolished, but should be treated in accordance with measures indicated in another section.

Fountains and ornamental ponds are frequent breeding places, and here the introduction of fish, is usually all-sufficient. It is necessary, however, to keep

the edges of such ornamental ponds free from vegetation where the larvæ may find refuge, and to choose aquatic plants whose growth will not permit of mosquito-larvæ protection.

Public dumps are great breeding places, because here are found old bottles, cans, boxes, bits of tin or iron vessels, and other objects in which water may accumulate for a time. Even a very small amount of water will make a breeding place for very many mosquitoes. It is quite possible for a broken portion of a pint bottle to contain enough water to yield literally thousands of mosquitoes.

Drainage measures really form a part of the consideration of the treatment of breeding places. Drainage on a small scale for the purpose of doing away with mosquitoes has been practiced for a long time, and in many parts of the country large-scale drainage with mosquito abolition in view is going on, notably in New Jersey and in California and results of great value have been reached.

While it is obviously best to abolish breeding places in the ways mentioned, it often happens that it is not possible to drain, and at least as a temporary expedient it becomes desirable to treat the water so as to kill the mosquito larvæ. Many substances have been tried, and, aside from certain proprietary mixtures, nothing has given such good results as the use of oils. Efforts to find oils that can be used to better advantage than petroleum have failed. Common kerosene of low grade, or of the grade known as fuel oil, is the most satisfactory as regards efficiency and price.

As to quantity, under still conditions, an ounce of kerosene to 15 square feet of surface space is about the right proportion, and in the absence of wind such a film will remain persistent for 10 days or slightly longer. Not only are larvæ and pupæ destroyed by the kerosene film, but many adult mosquitoes alighting on the surface of the water to drink or to lay their eggs are killed by it.

Small ponds can be sprinkled with an ordinary watering pot with a rose nozzle or pouring it out of a dipper or cup will be satisfactory.

In Panama a larvicide is being used which is made as follows: One hundred and fifty gallons of phenol is heated in a tank to a temperature of 212° F. Then 150 pounds of powdered or finely broken resin is poured in. The mixture is kept at a temperature of 212° F. Thirty pounds of caustic soda is then added and the solution is kept at the same temperature until a perfectly dark emulsion without sediment is formed. The mixture is thoroughly stirred from the time the resin is added until the close of the operation. One part of this emulsion to 10,000 parts of water is said to kill Anopheles larvæ in less than half an hour, while 1 part to 5000 parts of water will kill them in from 5 to 10 minutes. At a larvicide plant at Ancon 46,000 gallons of this mixture was made at a cost of $0.1416 per gallon. Although this mixture has been used to a large extent in Panama, crude oil was also used for streams having a fair velocity.

Natural Enemies of Mosquitoes—The common goldfish and silverfish destroy mosquito larvæ and should be put in artificial ponds. Top-minnows of several species have been introduced successfully in several localities and are great feeders upon mosquito larvæ.

There are many predatory aquatic insects that feed upon mosquito larvæ; others that catch the adults. Certain birds prey upon the adults, and bats also eat them.

Moths

Clothes moths are the prime offenders among fabric pests and there is no pest more hated by the housewife. The moths or "millers" most common about houses have a wing spread of about half an inch and are yellowish or buff-colored.

Harmless Moth Miller the Parent of a Destructive Worm—The moths, or millers as they are often called, have imperfectly developed mouth parts and could not feed upon fabrics if they desired. Their purpose in life is merely to lay eggs that develop into the worms or larvæ, which alone can cause destruction. Only the worm or larva of the clothes moth is capable of destroying fabrics.

Food of Clothes Moths—Clothes moths feed upon wool, fur, hair, feathers, and all fabrics manufactured from them. They also relish dried animal matter such as dead insects, including the dead of their own species, and untreated skins, beef meal, casein, etc. A single piece of hair-stuffed or feather-stuffed furniture may keep a house well stocked with clothes moths for years. Clothes moths almost never injure household fabrics or wearing apparel in daily or weekly use, or articles that are brushed, cleaned, or beaten once or twice a month. Furniture, on the other hand, may be in constant use and still be badly infested.

Clothes-moth eggs hatch most readily in warm summer weather in from four to eight days. During colder weather hatching may not take place for three weeks. In steam-heated buildings hatching does not require a much longer time than that taking place in warm summer weather.

The Larva—Of all the stages, the larva or worm stage—the only stage in which clothes moths damage fabrics—is the most susceptible to outside influences upon its growth.

While it is true that wearing apparel is not damaged by clothes moths if in daily or weekly use, the occasional appearance of moths in steam-heated houses in late winter makes it clear that moth eggs may be laid on susceptible articles at any time they are not in use and that if laid away without precautionary measures being taken to safeguard them they may be quite unexpectedly damaged in storage.

Remedies Recommended—There are effective methods for the control of fabric pests by the use of which the losses due to them can be reduced to a minimum. The fumigation of houses is not feasible or necessary for all, but careful attention to the details of cleaning, brushing, and, if possible, to sunning of fabrics immediately before they are stored with naphthalene or paradichlorobenzene or wrapped tightly in paper with these crystals is an effective and inexpensive remedy within the reach of everyone. Various effective remedies are enumerated here, together with a statement regarding conditions under which they are most effective.

The remedies here listed for the killing of fabric pests, or for protection against them, have been thoroughly tested and are in general use by the public. They can be recommended without reservation if used with an intelligent understanding of their good or bad qualities and in accordance with directions.

(1) Constant watchfulness. This must be the watchword for successful control. No treatment known to kill clothes moths already in fabrics will have any lasting effect in keeping other clothes moths from infesting the fabrics later if they are left exposed about the house. There is no treatment known that is practical that will render wearing apparel absolutely immune to attack.

(2) Thorough brushing, beating, and, if possible, sunning fabrics before any treatment is applied. These are important under all circumstances.

(3) Careful wrapping in unbroken paper.

(4) Naphthalene. Very effective in the form of flakes or moth balls for protecting clothing in closets, trunks, and tight chests.

(5) Paradichlorobenzene. Equal in effectiveness to naphthalene and used in the same manner.

(6) Camphor. For use in tight chests and trunks, but not as good as Nos. 4 and 5.

(7) Pyrethrum powder. Not as good as Nos. 4, 5, and 6.

(8) Cold storage. Rather expensive, but a certain method of protection against clothes-moth injury during the period in storage.

(9) Hydrocyanic acid gas. Excellent for fumigating entire houses or single *tightly sealed* rooms, but dangerous except when applied by an expert or careful and well-informed person.

(10) Sulphur fumes. Sulphur fumes generated by burning sulphur candles, purchased at drug stores. Likely to bleach wall paper and fabrics and will tarnish metals.

(11) Carbon disulphide. Excellent for fumigation of closets which can be tightly sealed, trunks, chests, and other tight containers. The gas is inflammable.

(12) Carbon tetrachloride. Excellent for fumigation of single rooms, closets, trunks, chests, and other tight containers.

(13) Cedar chests. Excellent for protecting clothing if used according to directions.

(14) Dry heat. Dependable if it can be applied.

(15) Hot water.

(16) Soap solution.

(17) Treatment of cracks and hiding places with gasoline, benzene, and kerosene.

(18) Dry cleaning.

Brushing, Beating, and Sunning—Too much emphasis cannot be placed on the value of frequent brushing, beating, sunning, and cleaning of articles subject to clothes moths attack. If clothing is thoroughly brushed every two weeks, it is doubtful if moths can affect it seriously. Carpets and rugs cleaned by strong vacuum cleaners and thoroughly brushed on both sides, or electrically cleaned, are freed from infestation if the work is properly done. Clothing dry-cleaned is also freed from infestation by the process. Once freed from infestation, clothes should be protected, if they are not to be used during the warm season, by being wrapped in paper or placed in tight chests or treated closets.

Careful Wrapping in Unbroken Paper—The public is familiar with " moth-proof " paper bags of various types that appear upon the market each summer. These bags if not torn and if properly used are excellent for keeping moths from reaching clothing. They are of no value in killing moths that may be in the clothing when it is placed in the bag, and those made of plain paper are just as good as those containing tar.

If these paper bags are not carefully sealed about the hanger, and spaces of one-fourth inch or more are left open, the moths have no difficulty in crawling into such openings, and if they do the bags are useless.

Ordinary firm wrapping paper is satisfactory, or several thicknesses of newspapers will serve. Clothes moths do not eat into paper to reach clothing. For this reason, if woolens and other fabrics subject to moth attack are cleaned and freed from moths by any of the methods mentioned above, they will remain safe if wrapped at once and tightly in several thicknesses of firm wrapping paper or in newspapers. Hats and other articles that will be damaged by tight wrapping can be protected by placing them in ordinary *unbroken* cardboard boxes, hat boxes, etc., and then sealing the covers of the boxes with gummed paper.

Naphthalene—Naphthalene is one of the safest and best materials for protecting fabrics against moth injury. To get definite results it must be used in tight chests, trunks, or other containers where the fumes given off by the slow evaporation of the crystals will be confined. If used in bureau drawers, in closets frequently opened, in pockets of clothing hung in closets, or in boxes which permit the fumes to escape, naphthalene is only partly effective and cannot be depended upon for absolute protection. The fumes of naphthalene will not injure man in the proportion in which he would be ordinarily subjected to them.

Naphthalene should be used at the rate of about 1 pound to each 6 to 10 cubic feet of space. One pound of good naphthalene flakes scattered between the folds of clothing in a trunk of average size should kill all stages of clothes moths. In tight chests of ordinary size the fumes given off by the slow evaporation of 1 pound of naphthalene will kill both young and well-grown larvæ of clothes moths and prevent moth eggs from hatching. If a good grade of naphthalene is used in tight containers there is no doubt as to the efficiency of naphthalene fumes. Too many persons expect naphthalene scattered about closet shelves or bureau drawers to be effective. It is not entirely so under such circumstances. If chests or trunks are not very tight much can be done toward making them so by sealing the cracks with adhesive paper or by papering them on the inside. If there is opportunity for the fumes to escape, use from 2 to 3 pounds of naphthalene to each 6 to 10 cubic feet of space.

Paradichlorobenzene—Paradichlorobenzene is a white, crystalline substance, which vaporizes slowly at ordinary temperatures, forming a gas apparently heavier than air. This gas is non-poisonous to man, but poisonous to clothes moths and other fabric pests when they are exposed to it in tight containers. The fumes do not injure fabrics. Paradichlorobenzene is similar in general appearance to naphthalene flakes. It appears to be quite as effective as naphthalene when used in accordance with directions for the use of naphthalene, and in the same amounts. It is a relatively new remedy which bids fair to become as well known in moth control as naphthalene.

Camphor—Camphor is used in the manner recommended for naphthalene and paradichlorobenzene, but is less effective than naphthalene. If of good quality and used at the rate of from one-half to 1 pound to each 5 cubic feet of space in tight containers, camphor will protect. All stages of clothes moths are killed by the fumes given off by the camphor; hence camphor, to be most effective, should be broken into small pieces and used in tight containers which will confine the fumes. While camphor does kill some eggs and larvæ when sprinkled in small pieces upon infested cloth in open containers such as bureau drawers, pockets in clothing, etc., it is not to be depended upon except where the fumes given off by evaporation can be closely confined with the clothing to be protected.

Pyrethrum Powder or "Insect Powder"—Pyrethrum powder if fresh, will kill clothes-moth larvæ. Clothing should be thoroughly dusted with the powder and placed in a tight container such as a chest or trunk, or wrapped well in unbroken paper. Pyrethrum powder soon loses its protective value on exposure to air, hence is not considered particularly effective for long storage, and is inferior to naphthalene or paradichlorobenzene. It is not always easy to obtain fresh pyrethrum powder.

Eulan—This substance is now offered for permanent moth-proofing. It is sold by the Interstate Chemical Company of New York and was developed in the laboratories of Boyer and Company of Germany. It is said to be a complex fluoride and is claimed to be non-poisonous. It is being used in the treatment

of fabrics before they are made into clothing, curtains, upholstery, etc., and renders them free from the attack of moths. Goods so treated are spoken of as being "*Eulanized*". It is also being sold in bulk for the use of the householder, 1½ ounces in a gallon of water producing a solution into which woolen articles of clothing may be dipped for permanent moth-proofing. Such articles are said to remain free from attack even after washing or dry cleaning. This solution may also be sprinkled on other clothing, carpets or upholstery, but the material must be well-wetted. Another proprietary article is Larvex. This is used and sold similarly to Eulan.

Cold Storage—The best method of protecting against injury by fabric pests of all kinds is cold storage. It is the best method because it eliminates all error on the part of the owner. Once in cold storage no injury can take place.

Fumigation of Entire Establishment with Hydrocyanic Acid Gas or Sulphur Fumes—In large houses with many carpets or rugs, much upholstered furniture and other fabric furnishings, and in tourist hotels and houses used only during the winter months but closed through the long, hot summer season, fabric pests may become very abundant and so generally established that they can not be reached easily by the local treatments recommended further on.

Fumigation by two methods can be used for the treatment of houses or hotels as a single unit—namely, with hydrocyanic acid gas and with sulphur fumes. *Formaldehyde fumigation is worthless for control of clothes moths or other fabric pests, notwithstanding general belief.* It is a good disinfectant for use after contagious diseases, but should never be employed for controlling fabric pests.

Hydrocyanic Acid Gas—Fumigation with hydrocyanic acid gas is the best known method of controlling fabric pests as well as other household pests, including the *bedbug*. It kills speedily and effectively.

Hydrocyanic acid gas is deadly to humans if breathed in concentrated form, and should be used only by an intelligent, careful, and well-informed person who understands the element of danger as well as the excellent features of the gas. Hydrocyanic acid gas should not be used in an apartment house, office building, or city block of houses unless neighboring parties are notified and are ready to vacate if necessary during the period of fumigation. For information on the method of fumigating with hydrocyanic acid gas write to the United States Department of Agriculture at Washington, D. C., for Farmers' Bulletin 699 or Reprint No. 673 of the United States Public Health Service.

Sulphur Fumes—Fumigation with sulphur fumes is a remedy well known to the public. Sulphur fumes will kill clothes moths, but must be used at the rate of about 13½ ounces of sulphur to each 1000 cubic feet of space. Fumigation should continue for a period ranging from 18 to 24 hours. *Remember* that there is some danger of fire in the careless use of sulphur candles, also that sulphur fumes may have a bleaching effect upon delicate fabrics and wall paper, and that they tarnish metals. Directions for burning sulphur candles usually are supplied by the manufacturer or the dealer.

Carbon Disulphide Fumigation—Carbon disulphide is an excellent fumigant for single rooms, closets, trunks, chests, and other tight containers. It is sometimes called "*high-life*". When exposed to the air it evaporates quickly, producing a foul-smelling gas about two and three-fourths times as heavy as air. While the liquid is not explosive or inflammable, the gas formed upon evaporation is. Because of this inflammable nature of the gas it must be kept away from fire in any form. The gas can be detected easily by its foul odor, but this odor disappears after thorough ventilation of rooms and fumigated articles. If used carefully and intelligently and in the proper

amounts carbon disulphide speedily and surely kills fabric pests in tight containers.

When used in small amounts about houses in accordance with directions, there is but little more danger than in the use of gasoline or benzine, with which the public is more familiar. For complete information regarding carbon disulphide and its use, write to the United States Department of Agriculture for Farmers' Bulletin 799.

Carbon Tetrachloride Fumigation—Carbon tetrachloride is a good fumigant for single rooms, closets, trunks, chests, and other tight containers. It is like carbon disulphide in that its gas is heavier than air. When carbon tetrachloride is used at the same rate as carbon disulphide, it is about one-half or one-third as effective. It has the great advantage over carbon disulphide that its gas is neither explosive nor inflammable, hence there is no fire risk in its use. Carbon tetrachloride is purchased at drug stores or from chemical firms in cans containing 1 or more pounds of liquid, and costs from 10½ to 30 cents a pound, according to the quantity purchased. It should be used at the rate of 8 to 12 pounds, or more, per 1000 cubic feet of space if containers are very tight. When the temperature is 70° F. or above, good results in killing clothes moths should follow if the quantities given above for carbon disulphide for the respective spaces are trebled. Since the gas is heavier than air, the liquid should be exposed in shallow dishes at the top of the container to be fumigated.

Cedar Chests—Chests made of the heartwood of red cedar, such as are found on the market, not only are so tightly constructed that the moths can not enter them when closed, but the aroma of the wood kills the newly hatched or young larvæ of the clothes moths.

The value of cedar chests in protecting clothing lies in the fact that they kill the newly hatched or young larvæ or worms of clothes moths. Cedar chests cannot be depended upon to kill the moths or millers, their eggs, or the worms after they are one-half to full grown or after they are 3 or 4 months old. Neither will the chests kill all the pupæ or chrysalids.

Dry Heat—Heat is now recognized as an effective agent in killing insects. All fabric pests will be killed in a very short time if rooms can be heated to a temperature of 130° F. long enough to permit all articles in the room to be thoroughly heated through to this temperature. Experimental work has demonstrated that even lower temperatures will kill the larvæ of clothes moths. All larvæ exposed in an incubator to 128°, 120°, and 110° F. died in 6, 11, and 31 minutes, respectively. At 105° F. 20 per cent were dead at the end of 31 minutes, while at 110° F. 30 per cent were dead at the end of 11 minutes. This killing power of heat can be readily utilized by ironing fabrics with very hot irons, or exposing them in super-heated rooms before they are put away for the summer.

The rays of the sun in summer can often be used to kill or drive clothes moths from fabrics. Thus clothes-moth eggs on flannel, exposed to the bright sun at 128°, 125°, 120°, and 110° F. were killed at the end of 6, 6, 11, and 31 minutes, respectively. Exposure to the sun at 110° and 105° F. for 31 and 11 minutes, respectively, did not kill the eggs. Well-grown larvæ of clothes moths in garments exposed for several hours to the hottest rays of the sun usually become restless and spin down from the garment. The old-time custom of sunning clothing to kill moths is based upon excellent experience.

Hot Water—Water boils at 212° F. At 115° a person finds water almost too hot to hold his hand in it. Fabrics that will not be injured by water can be freed of living clothes-moth eggs and larvæ by being dipped for 10 seconds

in water heated to 140° F. Care, however, must be exercised to have and keep the water at this, or a greater, temperature. Larvæ and eggs in flannel dipped for 10 seconds in water heated only to 122° F. remained unaffected.

Laundry Soap—Clothing washed with a strong solution of neutral laundry soap will be freed from clothes-moth larvæ and eggs, and if wrapped tightly in paper as soon as taken from the drying line, will remain free from moth attack.

Treatment of Cracks and Hiding Places with Gasoline, Benzine, or Kerosene—Any effective method of control for clothes moths and other fabric pests must take into due consideration the fact that woolen lint, hair, etc., accumulate in floor cracks, behind base boards, and in other such places. In this "dust" carpet beetles and clothes moths can and do subsist and migrate thence to other parts of the house. It is desirable, therefore, to reduce these hiding places as much as possible by the use of crack fillers such as can be purchased at paint shops, and treating them with kerosene, gasoline, or benzene. *Persons are warned against the careless use of these three liquids because of their inflammable nature.* If the premises are fumigated, clothes moths and other fabric pests in floor cracks and similar places are killed and the more laborious treatment by liquids is not necessary.

Impractical or Worthless Remedies—Below are listed certain worthless remedies, besides others not recommended to the housewife because of difficulty of application, partial effectiveness, impracticability, or lack of full information regarding their value.

Worthless Substances—The following substances often recommended for clothes-moth control are worthless:

Tobacco extracts containing nicotine and tobacco powder when used at reasonable strengths
Lavender flowers (scattered on)
Cayenne pepper
Allspice (dusted)
Angelica root (dusted)
Black pepper
Pyrethrum stems (dusted)
Lime, air-slaked (dusted)
Powdered sulphur (dusted)
Salt (dusted)
Quassia chips (dusted)
Borax (dusted)
Colocynth pulp (dusted)
Eucalyptus leaves (dusted)
Hellebore, white (dusted)
Formaldehyde (sprayed 1 to 10)
Sodium bicarbonate (dusted)
Sodium carbonate (dusted)
Lead carbonate (dusted)
Lead oxide (dusted)
Red cedar leaves (dried and placed in clothing)

Impractical Remedies—The following substances have considerable value if fresh or properly used, but they are impractical for one or more reasons and are not recommended, especially as among the remedies that can be recommended very highly there are a number that are easily within the reach of all.

Cedar Chips and Cedar Shavings—Ordinarily only partially effective, and never effective against adults or the half-grown to full-grown larvæ of clothes moths and carpet beetles. They soon lose their value and often become valueless before they are purchased by the retailer. Since the average purchaser of cedar chips and shavings has no certain method of determining their strength, it is better not to depend upon them to secure weak material and suffer loss from moths.

Gasoline—Gasoline sprayed on flannel kills clothes-moth eggs. Dipping clothing in gasoline will kill clothes moths and articles so dipped and coming direct from the dry-cleaning process may be considered freed, temporarily at least, from moth infestation. Of course as soon as garments are dried after

treatment they are subject to reinfestation. The use of gasoline for the treatment of wearing apparel most subject to moth attack is not advised for the average home because of the danger from fire.

Carpet Beetles

Carpet beetles, or so-called 'Buffalo moths', are common household pests usually associated in their destructive work with clothes moths.

Protection against carpet beetles can be secured in tight chests and trunks by the use of the crystals of naphthalene, paradichlorobenzene, or camphor, or by the fumigants carbon disulphide and carbon tetrachloride. Where infestation is general throughout a house or is serious in closets, it may be advisable to fumigate with hydrocyanic acid gas, carbon disulphide or sulphur, but none of these fumigation methods should be employed except by a person well informed regarding them. The foregoing remedies and others, such as cold storage, red cedar chests, heat and the treatment of infested floor cracks, are discussed under moths.

Bedbugs

Their Presence Explained—The presence of the bedbug in a house is not necessarily an indication of neglect or carelessness; for, little as the idea may be relished, this insect may gain access in spite of the adoption of all reasonable precautions. It is very apt to get into the trunks and satchels of travelers, or into baskets of laundry, and may thus be introduced into homes. Unfortunately, also, it is quite capable of migrating from one house to another and will often continue to come from an adjoining house, sometimes for a period of several months, gaining entrance daily. Such migration is especially likely to take place if the human inhabitants of an infested house leave it. With the failure of their usual source of food, the migratory instinct of the bedbugs is developed, and, escaping through windows, they pass along walls, water pipes, or gutters, and thus gain entrance into adjoining houses. In these or other ways anyone's premises may be temporarily invaded.

Origin; Common Names; Distribution—As with nearly all the insects associated with man, the bedbug has had the habits now characteristic of it as far back as the records run. It was undoubtedly of common occurrence in the dwellings of the ancient peoples of Asia. The Romans were well acquainted with it giving it the name Cimex. It was supposed by Pliny—and this was doubtless the common belief among the Romans—to have medicinal properties and it was recommended, among other things, as a specific for the bites of serpents. It is said to have been first introduced into England in 1503, but the references to it are of such a nature as to make it very probable that it had been there long before. Two hundred and fifty years later it was reported to be very abundant in the seaport towns, but was scarcely known inland.

One of the old English names was "*wall-louse*". It was afterward very well known as the "*chinch*", which continued to be the common appellation for it until within a century or two, and is still used in parts of this country. The origin of the name "bedbug" is not known, but it is such a descriptive one that it would seem to have been very naturally suggested. Almost everywhere there are local names for these parasites, as, for illustration, around Boston they are called "*chintzes*" and "*chinches*", and from Baltimore comes the name "*mahogany flat*", while in New York they are styled "*red coats*", and in the west "*crimson ramblers*".

The bedbug has accompanied man wherever he has gone. Ships are very apt to be infested with it and have been the chief means of its wide distribu-

tion. It probably came to this country with the earliest colonists; at least Kalm, writing in 1748–1749, stated that it was plentiful in the English colonies and in Canada, though unknown among the Indians.

General Characteristics—The bedbug belongs to the order Hemiptera, which includes the true bugs or piercing insects, characterized by possessing a piercing and sucking beak.

The "Buggy" Odor—The most characteristic feature of the bedbug is the very distinct and disagreeable odor which it exhales, an odor well known to all who have been familiar with it as the "buggy" odor.

Habits and Life History—The bedbug is normally nocturnal in habits and displays a certain degree of wariness, caution, and intelligence in its efforts at concealment during the day. Under the stress of hunger, however, it will emerge from its place of concealment in a well-lighted room at night, so that under such circumstances keeping the gas or electric light burning is not a complete protection.

The Bite of the Bedbug—The bite of the bedbug is decidedly poisonous to some individuals, resulting in a slight swelling and disagreeable inflammation.

To allay the irritation set up by the bite of the bedbug, peroxide of hydrogen, or dioxogen, may be used with good results.

Tincture of iodine either at ordinary or double strength is also a good counterirritant for use in cases of flea, mosquito, bedbug and other insect bites, but should be used with caution on the tender skin of small children and on those who are affected with or disposed to eczemic disorders.

The Bedbug and Human Diseases—In common with other insects which attack man and warm-blooded animals, it is entirely possible for the bedbug and its close allies to be transmitters of contagious human diseases, and already these insects have been shown to be possible carriers or transmitters of a considerable series of diseases, including infantile Kala-azar of Northern Africa and Southern Europe, relapsing fever of Africa and Europe, the Chagas fever of Brazil, tropical sore, plague, and possibly leprosy. In the case of these, and perhaps other diseases, the bedbug shares the responsibility of transmitter with other biting insects, such as body lice and fleas.

Remedies—Undoubtedly the most efficient remedy for the bedbug is to fumigate the infested house or rooms with hydrocyanic acid gas. This gas will penetrate into every crevice in the house or room where the bedbugs conceal themselves and has an immediate effectiveness which gives it an important recommendation, especially when the infestation is considerable or of long standing. This method of fumigation should be intelligently employed, as the gas is deadly poisonous. A bulletin giving directions for such fumigation has been issued by the Department of Agriculture, and was referred to under clothes moths.

The fumes of burning sulphur are also a very efficient means of control where the conditions are such that this method can be used, readily destroying the insect in all stages, including the egg. The treatment is inexpensive compared with the use of hydrocyanic acid gas and offers much less risk of danger to human beings. There is, however, a considerable risk of injury to household fabrics, furnishings, and wall papers from the strong bleaching quality of sulphur fumes. Two pounds of sulphur are recommended for each 2000 cubic feet of space, and the building should be closed for the treatment for at least 5 or 6 hours, or preferably for 24 hours. Sulphur candles may be used where available, or the sulphurous gas or fumes can be generated by burning the sulphur in a dish placed in the center of the room, and for protection set within a larger vessel. Thorough-going precautions must be taken to prevent acci-

dental overflowing or the starting of a fire, and after the fumigation the house should be given a thorough airing.

Other gases have been experimented with, such as formalin and the vapors of benzene, naphthalene, and camphor, but these gases are of little value. Similarly, insect powders are of little value, largely from the difficulty of getting them into the crevices and other places of concealment of the insects.

Of these simple methods of control perhaps the most efficient is in very liberal applications of benzene or kerosene, or any other of the lighter petroleum oils, introduced with small brushes or feathers, or by injecting with syringes into all crevices of beds, furniture or walls where the insects may have concealed themselves. Corrosive sublimate is also of value, and oil of turpentine may be used in the same way. The liberal use of hot water, wherever it may be employed without danger to furniture, etc., is also an effectual method of destroying both eggs and active bugs.

A remedy for the bedbug has been devised by Mr. R. H. Pettit as a substitute for hydrocyanic acid gas and sulphur, and is reported to have proved very successful. The preparation of this insecticide and its application is described as follows:

Alcohol is drawn through Pyrethrum in a funnel until the powder is well washed and a large part of the resinous principle extracted. To do this, the powder is placed in a large funnel with filter-plate and a layer of cotton wool at the bottom. An aspirator is attached and the alcohol is at first slowly and later rapidly sucked through six or eight times, during which operation it becomes highly colored. To this liquid as a basis, are added several oils to give permanence to the application. Both alcohol and Pyrethrum evaporate so quickly that it was thought best to carry in some heavier volatile oils whose effects would last several days or even weeks. The formula when completed stands as follows:

To the extract made by washing 400 Gm. of Pyrethrum with 2000 cc. of strong alcohol, are added:

50 Gm. of camphor.
150 cc. of cedar wood oil.
25 Gm. of citronella oil.
25 Gm. of lavender oil.

The application is best made with a large sized sprayer, one holding a pint or more and working with a piston instead of a rubber bulb. * * * To obtain the best results, repeat the treatment after about two weeks. We have tried this mixture repeatedly, and with uniformly gratifying results. Usually one application, if thoroughly made, put a period to the complaints, about eight or ten ounces being required in an average sleeping room. The odor remains some little time in a room, but is not disagreeable to the average person.

Ants

There are now in North America a considerable number of species of ants which under favoring conditions may inhabit dwelling places or other heated buildings.

The little red ant is the best known house species.

While ants are annoying because of their presence in foods, they do not disseminate disease.

Repellents—That it is possible to drive ants away from household supplies by the use of repellents, particularly camphor and naphthalene flakes or

powdered moth balls, has been asserted. The use of most of such repellent substances, however, in connection with food supplies, is impractical, and careful tests have indicated that such substances have only slightly repellent properties and bring comparatively little benefit.

The collection of ants by the use of attractive baits is frequently recommended. Perhaps as convenient a bait as any consists of small sponges moistened with sweetened water and placed in situations where they can be easily reached by the ants. These sponges may be collected several times daily and the ants swarming on them destroyed by immersion in hot water. It is reported also that a syrup made by dissolving borax and sugar in boiling water and distributed on sponges will effect the destruction of the ants in numbers. Remedies of this kind, however, are of doubtful value. They may be useful at the outset when the colonies are few and small and when most of the individuals may, by these means, be secured and destroyed. Very frequently however, the distribution of such baits will simply result in a more wide exploitation of a good forage ground and an actual increase of the ant nuisance.

A more efficient remedy, where it can be safely used, is a syrup poisoned with sodium arsenate, the idea being that the ants will collect this poison syrup and convey it to their nests, so that not only the ants which collect the syrup are ultimately killed, but the inmates of nests feeding on it also succumb. The formula for the preparation of this syrup is as follows: One pound of sugar dissolved in a quart of water, to which should be added 125 grains of sodium arsenate. The mixture should be boiled and strained, and on cooling used with sponges, as already described. The addition of a small amount of honey is said to add to the attractiveness to ants of this mixture. *Naturally the greatest precautions should be taken in preparing this syrup and in safeguarding it afterwards to prevent its being the cause of poisoning to human beings or domestic animals.*

Lawn Ants—In the case of lawn ants where only a small area with few nests are concerned, drenching the nests with boiling water or injecting a small quantity of kerosene or coal oil will be effective, and similar treatment will apply to nests between or beneath paving stones

Cockroaches

Roaches are among the commonest and most offensive of the insects which frequent human habitations.

Habits—In houses roaches are particularly abundant in pantries and kitchens, especially in the neighborhood of fireplaces, on account of the heat. For the same reason they are often abundant in the oven rooms of bakeries or wherever the temperature is maintained above the normal. They conceal themselves during the day behind baseboards or furniture, or wherever security and partial protection from the light are afforded. Their very flat thin bodies enable them to squeeze themselves into small cracks or spaces where their presence would not be suspected and where they are out of the reach of enemies. Unless routed out by the moving of furniture or disturbed in their hiding places, they are rarely seen, and if discovered make off with wonderful celerity, with a scurrying, nervous gait, and usually are able to elude all efforts at their capture or destruction. It may often happen that their presence, at least in the abundance in which they occur, is hardly realized by the housekeeper unless they are surprised in their midnight feasts. Coming into a kitchen or pantry suddenly, a sound of the rustling of numerous objects will come to the ear, and if a light be introduced often the floor or shelves will

be seen covered with roaches hastening to places of concealment. In districts where the large American roach occurs they sometimes swarm in this way at night in such number that upon entering a small room in which they are congregated one will be repeatedly struck and scratched on the face and hands by the insects in their frantic flight to gain concealment.

The domestic roaches feed on almost any dead animal matter, cereal products and food materials of all sorts. They are also said to eat their own cast skins and egg cases, and it is supposed that they will attack other kinds of roaches, or are, perhaps, occasionally cannibalistic. They will also eat or gnaw woolens, leather (as of shoes or furniture), and frequently are the cause of extensive damage to the cloth and leather bindings of books in libraries and publishing houses. The sizing or paste used on the cloth covers and in the binding of books is very attractive to them. The surface of the covers of cloth-bound books is often much scraped and disfigured, particularly by the German cockroach, and the gold lettering is sometimes eaten off to get at the albumen paste. On shipboard the damage is often very extensive on account of the vast numbers of cockroaches which frequently occur there, and there are reliable accounts of entire supplies of ship biscuits having been eaten or ruined by roaches.

The damage they do is not only in the products actually consumed, but in the soiling of everything with which they come in contact. They leave, wherever they occur in any numbers, an offensive, sickening odor, well known as the "roachy" odor which is persistent and can not be removed from shelves and dishes without washing with soap and boiling water. Food supplies so tainted are beyond redemption.

The roaches are normally scavengers in habit and may at times be of actual service in this direction by eating up and removing dead animal material.

One other redeeming trait has been recorded of them, namely, that they will prey upon that other grievous pest of houses, the bedbug.

The cockroach, however, is far too great a nuisance itself to warrant its recommendation as a means of eradicating even the much more disagreeable insect referred to.

Roaches undoubtedly are often spread from house to house by being introduced with supplies, furniture, goods, etc.

Remedies—Roaches may be controlled by the use of (1) poisons and repellents; (2) fumigants; and (3) trapping.

Poisons and Repellents—As just noted, roaches often seem to display a knowledge of the presence of poisons in food, and, not withstanding their habit of eating practically all sorts of food, a very little arsenic in baits seems to be readily detected by them.

Sodium Fluoride—One of the most effective simple means of ridding premises of roaches is dusting with commercial sodium fluoride, either pure or diluted one-half with some inert substance such as powdered gypsum or flour. Numerous practical tests conducted in lunch rooms, bakeries, milk-bottle exchanges, etc., have shown that with the use of this substance roaches can be completely exterminated with very little trouble and cost and with none of the possible dangers which attend the use of hydrocyanic acid gas, another efficient means of control referred to under the subject of fumigation. With the use of a dust gun or blower the sodium fluoride can be thoroughly dusted over the shelves, tables, floors, and the runways and hiding places of the roaches.

Borax—Powdered borax enters into the composition of many of the so-called roach powders. This substance may be used either pure as a poison or repellent, or mixed with some other substance to render it attractive to the

insects. Several correspondents have reported great success from the use of a mixture consisting of 1 part powdered borax to 3 parts of finely pulverized chocolate, this mixture to be freely sprinkled about the infested premises.

Pyrethrum—Another common remedy consists in the liberal use of Pyrethrum powder or Buhach. This is at best only a temporary expedient, but if persisted in considerable relief will be gained. To be at all effective it must be fresh and liberally applied. The roaches are often paralyzed by it rather than killed outright, and the morning after the application all paralyzed and dead roaches should be swept up and burned.

Sulphur—Flowers of sulphur dusted about where roaches abound has also proved very effective as a repellent.

Phosphorus—Of the proprietary substances, perhaps one of the oldest and most efficient is a form of phosphorus paste. It consists of sweetened flour paste containing 1 to 2 per cent of phosphorus, and may be distributed on bits of paper or cardboard placed in the runways of the roaches.

All phosphorus pastes are deadly poisons if taken internally.

Fumigants—Hydrocyanic Acid Gas—Hydrocyanic acid gas fumigation is a thoroughly effective means of ridding premises of roaches, but involves considerable cost, difficulty of application, and the necessity of taking *extreme precautions on account of the deadly effect of the gas on higher animals, including human beings.* (See article on *Moths*, page 1843.)

Carbon Disulphide—Wherever roaches infest small rooms or apartments which may be sealed up nearly air-tight, and also on shipboard, the roach nuisance can be greatly abated by the proper use of carbon disulphide. This substance, distributed about a pantry or room in open vessels, will evaporate, and, if used at the rate of 1 pound to every 1000 cubic feet of room space, will destroy roaches. Unless the room can be very tightly sealed up, however, the vapor dissipates so rapidly that its effect will be lost before the roaches are killed. The hatches of ships, especially of smaller coasting vessels, may be battened down, a very liberal application of carbon disulphide having been previously made throughout the interior. If left for 24 hours the roaches and all other pests will unquestionably have been destroyed.

Pyrethrum Fumes—A safer remedy of the same nature consists in burning Pyrethrum in the infested apartment. The smoke and vapors generated by the burning of this insecticide are often more effective in destroying roaches than the application of Pyrethrum in the ordinary way as a powder. There is no danger of explosion, and the only precaution necessary is to see that the room is kept tightly closed for from 6 to 12 hours.

Trapping—Various forms of traps have been employed very successfully. These devices are all so constructed that the roaches may easily get into them and can not afterwards escape. The destruction of the roaches is effected either by the liquid into which they fall or by being doused with hot water.

The House Centipede

The house centipede, particularly within the last 20 or 25 years, has become altogether too common an object in dwelling houses in the Middle and Northern States for the peace of mind of the inmates. The creature is not a true insect, but belongs to the Myriapoda, commonly known as centipedes or "thousand legs", and is sometimes called the "skein" centipede, from the fact that when crushed or motionless it looks, from its numerous long legs, like a mass of filaments or threads.

The Bite—The popular belief is that this centipede is extremely poisonous, and, as it belongs with the poisonous group of centipedes, it can not be ques-

tioned but that the bite of the creature is probably somewhat poisonous as well as painful, though the seriousness of the results will be dependent, as in all similar cases, on the susceptibility of the patient. Prompt dressing of the wound with ammonia will greatly alleviate the disagreeable symptoms.

Remedies—It can be best controlled by promptly destroying all the individuals which make their appearance, and by keeping the moist places in houses free from any object behind which it can conceal itself, or at least subjecting such locations to frequent inspection. In places near water pipes, or in storerooms where it may secrete itself and occur in large numbers, a free use of fresh pyrethrum powder is to be advised.

The Silverfish

The silverfish is that glistening, silver or pearl gray insect with three long tail-like appendages, that one finds when books, papers, clothing, etc., are suddenly moved. From the dark recesses thus exposed to light the silverfish glides quickly out of sight, often thwarting all attempts to catch it. In fact, this insect is an adept at dodging, and when actually in contact with the fingers, the slick, shining body easily slips from the grasp. On account of its glistening body, its quick, gliding movements, and its ability to appear and as quickly and mysteriously disappear, it has received a number of popular names, among which are *silverfish, slicker, silver louse, silver witch, sugarfish, woodfish,* and *bristle-tail.* It occurs in both Europe and America, and, like most of the insects of the household, is well-nigh cosmopolitan in its distribution.

There are a number of different kinds of silverfish, perhaps the most common, aside from the subject of this paper, being the "*firebrat*". This is a heat-loving species that is to be found in greatest numbers about fireplaces and bake ovens and may be distinguished from the common silverfish by the dusky markings on its back.

Habits and Injury—Because the silverfish always shuns the light and has the ability to run very rapidly to places of concealment, it is not often seen and may become very abundant and cause considerable injury before its presence is noticed. The rapidity with which it runs and the slipperiness of its body, due to the scales that clothe it, make it almost impossible to catch the silverfish without crushing or damaging it.

The silverfish is one of the most serious pests of libraries, particularly in the bindings of books. Frequently it eats off the gold lettering to get at the paste beneath, or gnaws off the white label slips glued on the backs of books. Heavily glazed paper and museum labels are sometimes disfigured or destroyed by the feeding of the pest upon their surfaces. In some cases books printed on heavily sized paper will have the surface of the leaves a good deal scraped, only those portions covered by the ink being left unattacked.

The silverfish also will eat any starched clothing, linens, or lace or muslin curtains, and has been known to do very serious damage to silks which had probably been stiffened with sizing. By eating the paste from the back of wall paper the silverfish sometimes causes the wall paper to scale off. The pest has been reported feeding upon carpets, plush coverings of furniture, and even upon certain vegetable drugs.

It is seldom that the silverfish causes damage except where its food has been left undisturbed for long periods packed away in drawers, closets, bookcases, or other such places. The pest multiplies rapidly in houses closed for the summer. It likes warmth and does little damage during winter in the North, although in the South it is active throughout the year ,much as are cockroaches.

Remedies—As stated, silverfish cause injury to clothing, books, etc., in their attempts to get at the starch or glue in them. Advantage may be taken of this craving for fabrics and other articles containing these substances to poison the insects by slipping into all the crevices where they occur—in bookshelves and backs of mantels, under washboards, and in the bottoms of drawers—pieces of cardboard on which a thin boiled starch paste, poisoned with powdered white arsenic, has been spread and dried. In making the paste the following formula should be used: Flour, 1 pint; white arsenic, ½ to ¾ ounce; water. The arsenic should be added to the flour and sufficient water used to make a thin paste by boiling. Complete relief has been secured by this measure. *Great care should be taken to keep the arsenic, the poison paste, and the poisoned bits of cardboard where young children will not get hold of them.*

Pyrethrum, or buhach powder, dusted upon bookshelves or other places where it can be used, is of value; but it must be renewed often, for it loses its power as an insecticide after long exposure to air.

For starched clothing and similar objects liable to injury, frequent handling and airing and the destruction by hand of all silverfish discovered are to be recommended, in addition to the remedies noted above. Little damage is likely to occur in houses except in comparatively moist situations or where stored objects remain undisturbed for a year or more.

Book-lice

Book-lice, or psocids, are the tiny white or grayish-white insects, scarcely as long as the width of an ordinary pinhead, and often much smaller, that scurry across the pages when old, musty books are opened.

Unless they are present in annoying numbers, it is probably not worth while to worry about book-lice, for many exist out of doors and can get in through cracks and through the mesh of ordinary screens. With the coming of cold weather, or in late fall and winter, book-lice die off, but may leave behind eggs that will hatch the following spring.

How to Control Book-lice in Houses—Where only a few book-lice are present, a thorough cleaning, airing, and drying of the room is all that is needed, provided the source of infestation is within the room itself. As many as possible of the objects in the room should be removed and thoroughly sunned on a bright day. The room should be heated to a temperature of 120° to 140° F. for several hours. Psocids are soft-bodied insects, and succumb to a prolonged drying due to heat. Where rooms are located on the ground floor in loosely constructed buildings in shaded and damp situations, as are many summer cottages, so many psocids come in from the outside that almost no treatment will entirely rid a room of them.

When book-lice swarm in alarming numbers over and throughout a room the breeding places should be located at once. If the source is old straw or husk fillings of mattresses, these should be removed and burned whenever possible. Thorough fumigation with the fumes of sulphur, 1 pound of sulphur being burned for each 1000 cubic feet of space, is effective. Where other pests are present, such as bedbugs, and where the bleaching effects of the fumes can be disregarded, as in barracks, 5 pounds of sulphur will prove effective. During fumigation the rooms should be kept closed as tightly as possible, and after five or six hours opened from without and thoroughly aired. Fumigation with hydrocyanic acid gas is very effective, but dangerous in the hands of inexperienced persons.

Closets, boxes, trunks, and sometimes even entire rooms, where infested

objects are kept near the floor, can be fumigated satisfactorily with carbon disulphide. (See page 1843.) In addition to cleanliness and plenty of sunlight, heat or fumigation, wherever it can be applied, will yield the best results, if the source of infestation has been removed.

Fleas

Of the approximately 500 species of fleas known to exist, less than one dozen are of special interest as pests to man and domestic animals, but any individual of one of these few species, when bent upon satisfying its appetite, fully occupies the attention of its chosen host.

The human flea, dog flea, cat flea, sticktight flea or chicken flea, and the rat fleas (which carry the bubonic plague), are the principal species that annoy man and domestic animals in the United States.

Fleas as Pests in the Household—In the eastern part of the United States the dog flea is the species of greatest importance as a household pest. Houses, particularly those vacated for some time during the summer months, have been found to be literally over-run by the pests.

In portions of the South and West the human flea is the one primarily responsible for house infestations. Although the host relationship of these two species is somewhat different, the same methods of control are applicable, for the most part, to both. When comparatively small numbers of fleas are found on people in houses, breeding places should be sought out of doors in sheds or barns frequented by dogs and cats, especially if the house is kept clean and animals do not frequent it.

Dog and Cat Fleas—Dogs and cats are infested by two very closely related species of fleas, and these appear to feed more or less interchangeably on the two hosts, as well as occasionally on man and other animals. While they cause these hosts much annoyance and, as has been pointed out, are also responsible for the infestation of dogs by tapeworms, serious injury seems to be rare. In the case of valuable dogs and cats, however, it is often desirable to rid them of fleas, and in all cases where these animals are closely associated with man the control of the fleas upon them is of importance.

The Relation of Fleas to Bubonic Plague—During recent years bubonic plague has been introduced into the United States on both the Pacific and Gulf Coasts. The infestation in California has persisted for a number of years, although closely held in check through the efforts of the Public Health Service and the State board of health. The disease around San Francisco not only persisted among the rats, but gained a foothold among ground squirrels in the counties adjacent to San Francisco Bay.

During the year 1914 the disease broke out in New Orleans, but strict quarantine measures and an energetic campaign against the rats kept the malady from spreading and limited the number of human cases.

With the reduction in numbers of rats and mice there is a correspondingly great decrease in the numbers of the species of fleas which infest them and which may play a part in carrying bubonic plague. The cleaning up of the breeding places of rats and the destruction of their nests will accomplish the extermination of a large number of fleas in the immature stages.

Persons resident in districts where plague occurs among the ground squirrels should remember that there is danger of infection from the bites of fleas which infest these animals.

Remedies for Household Infestations—As has been pointed out, the dog flea and the human flea are the two most important species invading the

habitations of man. It has also been suggested that the adult fleas feed more or less on cats and dogs and that the immature stages develop in the cracks of floors and beneath houses. It, therefore, is apparent at once that two steps are necessary to cope with the pest: (1) The destruction on the host of the adults which are producing the eggs, and (2) the clearing out of the immature stages which are breeding in or under the house.

How to Kill Fleas on Cats, Dogs, and Hogs—One of the most successful methods of killing fleas on cats and dogs is to wash the animals thoroughly in a tub containing the proper proportion of a saponified coal-tar creosote preparation, of which there are a number on the market, known as "stock dips", etc. The animal should be scrubbed thoroughly, special precaution being taken that the fleas on the head are well soaked, as many rush there to get away from the parts that are covered with the solution. After the animal has been in the bath for about 5 or 10 minutes it may be removed and allowed to dry. In the case of cats, especially if tender skinned, the preparation should be washed out of the fur with soap and warm water soon after the animal is taken out of the solution.

In addition to the destruction of all fleas present, this washing cleanses and deodorizes the fur and also aids in the healing of any wounds which are present.

The thorough washing of infested animals in kerosene emulsion is a cheap and satisfactory method of destroying fleas. Five gallons of this emulsion may be made by dissolving 2 ounces of washing soap in 1 quart of hot water and when brought to a boil removing it from the fire and adding 2½ pints of kerosene. The mixture should be agitated violently with an egg-beater or something of the sort. This should result in a milky mass from which the oil does not separate. Water is then added to make 5 gallons. Free kerosene will burn animals, and if any separates out the mixture should be reheated, care being taken to avoid spilling it on the fire or permitting it to boil over, and then it should be beaten again.

Other methods of destroying fleas on cats and dogs have been recommended. Among these the careful rubbing into the hair of powdered naphthalene or moth balls has been found effective. Pyrethrum or Persian insect powder is used in the same way. Both of these materials stupefy the insects and cause them to come to the surface of the hair or actually drop out. The animals should be treated on papers spread on the floor and the insects burned after the dusting is completed.

Recent experiments with the use of the powdered roots of certain tropical plants known as *derris* indicate that this drug when fresh is exceedingly effective in destroying fleas on animals. All fleas on a dog will be destroyed by one application of 1 gram or about three-fourths of a level teaspoonful of the powder. It is suggested that the material be mixed at the time it is used with two parts of flour or cornstarch and dusted into the hair of the animal, especially along the back and neck, with a shaker.

The skin of cats is much more easily injured with chemicals than that of dogs; hence, any preparation used should be weaker when used on cats than on dogs.

Fleas on hogs may be destroyed by dipping the animals in a vat containing one of the creosote dips used for the hog louse or by sprinkling crude petroleum on them when they are eating.

How to Destroy Fleas in Immature Stages—Following the ridding of infested animals of adult fleas, it is important to destroy the immature fleas, which are constantly becoming full grown and reinfesting animals and annoying man.

When adult fleas are very numerous it is advisable to kill them before proceeding to destroy the young. Experiments of a practical nature prove that very striking results may be accomplished by the spraying of an infested area, whether in a basement, chicken house, barn or feed lot, with creosote oil. A light spraying kills the adult fleas almost instantly and apparently has some destructive effect on the immature stages.

Creosote oil is derived from coal tar and is used as a wood preservative. It is comparatively cheap, retailing at about 50 cents per gallon. Unfortunately it is not generally available at present and it is somewhat variable in composition, especially in regard to the amount of tar acids present. The best results are secured with a product containing from "12 to 20 per cent tar acids". Where there is grass or shrubbery to be considered, kerosene emulsion should be substituted for the creosote oil, as the latter kills vegetation. Care should also be taken not to strike animals directly with the material, as it is rather caustic. In houses the use of flaked naphthalene as described in a later paragraph will permit the work of cleaning to proceed without annoyance from adult fleas.

In household infestations usually it is found that the breeding takes place in the cracks of floors or beneath carpets or in rooms which are not frequently swept, but which may be visited by pet dogs and cats. The carpets and rugs should be removed, the floors thoroughly swept, and all of the dust thus obtained burned, as it contains many of the eggs and maggots of the fleas. Then the floor should be scrubbed with strong soapsuds or sprinkled with gasoline, care being taken to avoid having fires about during the procedure. After the floor coverings are thoroughly aired and beaten they may be returned but it is desirable before putting them down to sprinkle the floor with naphthalene crystals or pyrethrum powder.

In flea-infested regions it is advisable to avoid the use of mattings and carpets. These may be supplanted by rugs or oiled floors, which facilitate frequent sweeping and make the destruction of the immature stages easier if an infestation becomes established.

Among other methods for destroying the fleas in houses the following have been tried and recommended: Scatter 5 pounds of flake naphthalene over the floor of an infested room and close the doors and windows tightly for 24 hours. After this period the naphthalene may be swept into another room, and so on, thus making the treatment inexpensive. The free use of alum, both in the powdered form sprinkled over carpets and rugs and by dipping papers in an alum solution and placing them under the rugs, is said to give satisfactory results. The fumigation of houses with sulphur fumes or hydrocyanic acid gas kills all fleas present and in addition destroys the rats and mice. When sulphur is to be employed the infested building should be closed up tightly and the material used at the rate of 4 pounds to each 1000 cubic feet of space. If the immature stages have been destroyed by the methods mentioned, 2 to 3 pounds of sulphur per 1000 cubic feet of space will be sufficient to destroy the adults.

When house infestations are derived from fleas which breed beneath or around houses, the first step is to clean out all the loose material in which fleas may be breeding and burn it. Then common salt should be scattered about and thoroughly wet down. A second wetting two or three days later usually will accomplish complete destruction, but if this is not found sufficient, one or two additional wettings may be given. Where crude petroleum is cheap and especially where water can not be applied easily, sprinkling the ground with a liberal amount of this oil will give good results. The free use of lime on the cleaned areas also apparently destroys many immature fleas. In exceptional cases lawns become infested, and fleas breed out around the roots of the

grass. It is impracticable to apply chemicals in such situations, but much may be done to check the breeding by cutting the grass exceedingly short and thus exposing the young fleas to the heat of the sun, which will usually accomplish their destruction. In certain sections it has been found feasible to destroy flea infestations in barns and hog runs by diking the infested areas and pumping water in so as to flood them entirely.

Trapping Fleas—Following the treatment of host animals and the thorough cleaning up of the premises, as has been outlined, many of the remaining adult fleas may be caught by the use of traps.

There seems to be some virtue in the use of lights at night for attracting the adult fleas. A small lamp set in a pan of water covered with a film of kerosene may be used for this purpose.

It has been found that a considerable number of fleas may be collected about a room or cellar by allowing an animal such as a guinea pig or cat to be free in the room. The fleas thus concentrated on the animal may be destroyed by the methods mentioned under the heading, "How to kill fleas on cats, dogs, and hogs". In districts where the plague is known to exist and it is desirable to catch the few fleas about the premises, this method is of some value.

Isolating and Repelling—It has been determined that the greatest horizontal distance fleas can jump is about 13 inches, and they can not jump more than one-half of this distance vertically. It is possible, therefore, to prevent them from gaining access to a bed by placing sticky fly paper about 13 inches wide on the floor around the bed, provided fleas are not breeding out under it. It is also possible to keep fleas out by placing the legs of the bed in pans of water covered with a film of kerosene, if the bedding is prevented from reaching near the floor.

Many different substances have been advocated as repellents for fleas. Among these may be mentioned such plants as pennyroyal and boughs and chips of pine. Naphthalene crystals and pyrethrum have also been employed for dusting between the sheets in order to repel the fleas from bedding, and these substances, as well as oil of pennyroyal and oil of tar, may be used about the household to drive out the fleas.

It should be borne in mind that the methods of trapping and repelling just discussed are secondary to the more important measures of destroying the breeding places and freeing hosts from fleas.

Treatment of Flea Bites—In regions in the United States where the plague is not known to occur no special concern need be felt regarding flea bites. When feeding, the fleas inject a salivary secretion which tends to produce inflammation at the site of the puncture. Usually the bites result in small inflamed spots, but occasionally, where the pests are very numerous and in the case of susceptible individuals, more general inflammation may occur, sometimes followed by swelling and, occasionally, especially after scratching, by ulceration.

Those who are especially annoyed by the bites will find that various cooling applications will give relief. A 3 per cent solution of phenol in water applied to the bites will be beneficial, and such substances as menthol, camphor, and carbolated vaseline will be found to allay the irritation. Iodine in the form of a tincture, if applied to the bites, will alleviate the irritation, but should not be used by persons afflicted with any form of eczema, or applied to the tender skin of young children, as it may stimulate the eczemic eruptions or blister the skin, causing undue annoyance.

How to Get Rid of Rats

The large number of failures to exterminate rats is due in part to the use of inefficient methods, but half-hearted effort and easy discouragement are more often responsible. Rats can not long survive a concerted and sustained onslaught. They can be eliminated from any ordinary building or farm by the intelligent and judicious use of the methods here described.

The all-important measures to be taken are the removing of food and shelter from rats, poisoning and trapping them, and under certain conditions fumigating their burrows. These measures should be undertaken not only by individual effort but also through community coöperation.

Poisoning—The most efficient means known to the department for detroying rats is by poisoning, and poison is recommended for the purpose whereever it can be used with safety. Powdered barium carbonate is an inexpensive mineral, and seems best adapted for poisoning rats.[1] It is both odorless and tasteless, and baits containing it are readily taken by these pests. It also has the advantage of being slow in its action, so that rats affected by it usually have time to leave the premises in search of water or to return to their burrows before they succumb.

The following directions for using barium carbonate have been carefully worked out and should be closely followed to obtain the best results.

Kinds of Bait—A variety of baits used separately not only gives the rat a choice of foods but tends to make it less suspicious. One kind of each of the following classes of food mixed with barium carbonate is recommended:

(1) *Meat or Other Animal Substance*—Hamburg steak, sausage, fish, liver, bacon, or cheese.

(2) *Vegetables and Fruits*—Thin slices of muskmelon, apple, tomato, or cucumber; canned corn, or squash or pumpkin seed; or mashed banana, boiled carrot, or baked sweet potato.

(3) *Cereals*—Rolled oats, bread, corn meal, flour, or cake. Kitchen scraps and garbage can be worked into the ration to advantage.

Baits should be fresh and preferably of good quality.

How to Prepare Baits—The powdered barium carbonate should be thoroughly mixed and worked into the soft baits in the proportion of 1 part of the mineral to 4 parts of the selected food. Add water when necessary to make the baits moist. Baits moistened to the consistency of soft mush are particularly acceptable to rats in dry weather.

Barium carbonate should be sifted over sliced baits and rubbed well into them with the fingers or a knife. The slices should be thin and should be moistened if necessary in order to attain as nearly as possible the 1 to 4 ratio. Soft baits may be mixed with the hands or with a spoon.

How to Distribute Poison—A teaspoonful, or its equivalent, of each of the three or more kinds of baits prepared, should be exposed in places frequented by rats. In buildings baits should be set on strips of paper or boards where they may be easily removed.

A convenient and successful method of exposing baits is to place a teaspoonful in each of a number of small paper sacks and drop them in places accessible to rats or frequented by them. The sacks should be closed by twisting the top. Bait distributed in this manner serves to allay the suspicion of rats and will be taken by them more readily than if exposed in the open. It is

[1]Other poisons commonly used are phosphorus, arsenic, and strychnine. Phosphorus is attended with danger from fire. Arsenic is uncertain in its action; while strychnine is readily detected by rats and is too rapid in its action to make its use desirable in buildings. Barium carbonate has the advantage of being not only of proved effectiveness, but also inexpensive and relatively safe.

better not to place the sacks near or at rat holes, but rather to scatter them promiscuously about. The sacks are usually carried into burrows or behind objects, where the contents are eaten in comfort and are more nearly consumed than in the open. In public places, where there is a possibility that the bait will be disturbed by people, the sacks should be labeled " POISON".

Baits of three or more kinds should be exposed in groups. Where rats are abundant, baits may be exposed at intervals of 10 to 20 feet. Uneaten baits should be picked up the following morning and destroyed. If left exposed in warm places more than one day, baits will sour, and the resulting acid will gradually transform the barium into a bitter and highly objectionable form. Continue to distribute fresh baits in less quantity each night, repeating those that are eaten freely, and replacing those less relished by others in the same class, until the rats disappear or until no further baits are taken.

In stubborn cases it may become necessary to resort to prebaiting in order to dispose of old and cunning rats. This consists in exposing unpoisoned or fresh foods every night until rats take them freely, and then substituting the poisoned baits.

Poison used in poultry inclosures should be exposed in places inaccessible to chickens, as behind or under boxes, and it should be very wet or of such nature that the rats can not drag it from cover.

Caution—Barium carbonate is a relatively mild poison, but the danger from accidents can not be over emphasized. *Keep it out of the reach of children and irresponsible persons and from domestic animals and fowls.*

Antidote—Give an emetic consisting of either mustard or salt dissolved in warm water, or induce vomiting by inserting the finger in the back of the throat. Follow vomiting with a liberal dose of Epsom or Glauber salts.

Trapping—Trapping rats, while equally as effective as poisoning, requires more skill and labor. It is recommended where the use of poison seems inadvisable.

Careful attention to detail is necessary in trapping rats, as the measure of success will depend largely upon the skill and resourcefulness with which the traps are handled.

While numbers of the more complicated traps and devices for catching rats are sometimes useful, the simple and inexpensive snap trap, sometimes called " guillotine", " spring", or " break back", has easily proved the most effective and consistent rat catcher. There is little choice between the standard makes of this style of trap, and selection should be governed by strength and apparent durability. The essential is a trigger that will release the spring at a very light touch. The trigger should also be provided with a hook or other means of holding the bait fast. Large triggers have an advantage over small ones, as they have a greater surface for the rat to step on, and especially as they are better adapted for use along walls and narrow runways, where rats may be trapped successfully without baiting.

In trapping, as in poisoning, the kinds of baits used are of prime importance and to give the rat a choice of foods and to lessen its suspicion the same principle of variety is equally applicable.

To get the best results the following directions for baiting and setting snap traps should be carefully observed.

Kinds of Bait—Rolled oats, fried bacon, bread, and toasted cheese are the baits most frequently used. Baits which will easily adhere to the trigger hook, as fried bacon, raw or cooked meats, fish, nut meats, cheese, apples, or carrots, are recommended for general use. These may be made more attractive by sprinkling rolled oats or corn meal lightly over the trap. Almost any food

suitable for human consumption will appeal to the gluttonous appetite of the rat, so that there should be no lack of variety.

Where to Set Traps—Rats rely on concealment for protection and avoid open spaces as much as possible. The best place to set traps, therefore, is close to walls, behind objects, in dark corners—anywhere that a rat in striving for concealment would run. Traps should be set in such a manner that the rat in following its natural course will pass directly over the trigger. For example, in setting along a wall the trap should extend from the wall at right angles, the trigger end close against it. Boards may be leaned against the wall, thus forming a natural runway for rats and a good setting place for traps.

How to Set Traps—Baits should be large and fastened securely to the trigger by means of the trigger hook or tied to the trigger with thread or fine wire, so that when attempting to remove them the rat will be sure to spring the trap. Traps should be set very lightly, so that they will spring easily.

After most of the rats have been caught, the others sometimes leave the premises. More often, however, the remaining rats are not frightened away, but avoid baits and prove very difficult to catch. Strategy must be used in outwitting such individuals. The most successful method is to camouflage the traps.

Traps set on the ground may be sunk slightly below the ground level. A small piece of paper or cloth should then be placed over the trigger end of the trap to prevent dirt from getting underneath and clogging the action, and the whole should be lightly covered with fine earth or sawdust.

The same method may be employed on hard floors, by burying the traps in a shallow pan of meal, sawdust, or grain. A trap set in this way may be placed in a runway without baiting, or several pieces of bait may be scattered over it. In stubborn cases, food may be exposed on pans of meal until the rats take it readily, when the traps should be set in the meal. Stones, boxes, or boards will often aid in directing an unsuspecting animal along an easy path over a trap.

General Trapping Instructions—The presence of an abundance of food makes trapping much more difficult. Before starting a trapping campaign remove all accessible food and eliminate the sources of supply.

Plenty of traps should be used. Trying to catch a hundred rats with half a dozen traps will make those not caught suspicious and dishearten the trapper long before the job is completed. A dozen or more traps for a heavily infested dwelling and from 50 to 100 or more for farms and larger buildings are not too many. It is important that a sufficient number of traps be obtained to make the campaign short and decisive. The cost of traps is little compared with the loss occasioned by rats.

Traps should be kept in good working condition and should be carefully examined before setting to insure their instant operation. They should be kept reasonably clean, and if they become very foul, should be boiled and scraped. When trapping is done on a large scale, especially in damp places where metal parts of the traps may rust, an occasional dipping in melted paraffin will lengthen their usefulness, cause them to spring more easily, and have a deodorizing effect.

Trapping rats in larger buildings and on farms should be assigned to a man with a natural aptitude for such work. When interest is taken, only slight training is necessary for some men to become proficient in the work. Such men should be encouraged to persistent effort.

Fumigants and Deterrents—*Carbon Bisulphide*—In many places rat burrows may be fumigated with carbon bisulphide and the rats thus destroyed in the ground. This method is effective in fields, along ditch banks and levees,

around farm buildings, and in dirt cellars, providing the burrow is dug in solid earth. The gas is more effective in heavy damp soils and in wet weather.

A wad of cotton or other absorbent material should be saturated with 1 ounce (2 tablespoonfuls) of carbon bisulphide and thrown or pushed as far as possible into each burrow; all burrow entrances should then be closed with moist earth to prevent the escape of the gas. A long pair of forceps is convenient for handling the absorbent material.

Caution—*Carbon bisulphide is highly inflammable and explosive and should not be approached by fire.* It evaporates rapidly and should be kept in an air-tight container.

Gasoline Engine Exhaust—Use of the exhaust of an automobile, tractor, or other gasoline engine in fumigating rat burrows is entirely practicable when there are only a small number of holes. The exhaust is directed into the rat burrow by means of a hose and the entrance around the hose is sealed with damp earth. The carburetor is adjusted to obtain a rich mixture and the engine allowed to run at moderate speed for 10 minutes or more. This method may also be used successfully in destroying rats beneath floors or in other places where a concentration of the gas can be obtained.

Naphthalene Flakes—In seed warehouses and similar structures where sacked grain is stored temporarily, or otherwise, it has been found that a liberal supply of flake naphthalene, scattered on the floor about the stacked grain and over the bags, is objectionable to rats and will keep them away. In the seed distribution work of the Bureau of Plant Industry of this department the need of a cheap repellent was felt because of the fact that the many tons of seeds sometimes on hand could not be placed in rat-proof rooms. Flake naphthalene was tried in 1912 and proved so satisfactory that it has been used continuously ever since. The flakes are scattered abundantly over bags of seed as they are stacked and also in bins and rooms containing filled packets. The naphthalene does not damage the seed in any way and can be used with impunity in any reasonably tight building. Because of its odor, the use of the naphthalene flakes is not recommended in places where food and feed-stuffs are stored, unless the nature of the material is such that it can be thoroughly deodorized by airing before use.

Rat-Proofing—Poisoning, trapping, and other extermination methods carefully applied will give relief of more or less uncertain duration, but so long as there are rats in a neighborhood and they find it possible to get inside a building, there is always the danger of reinfestation. The only sure and final remedy for the rat nuisance is rat-proof construction. Without it rats will get into a house, by gnawing if necessary, in order to locate an available and easily obtained food supply. The rat must be built out.

Most modern buildings and many older ones are so constructed as to be proof against the ingress of rats or could be made so at a relatively small cost. Owners of large warehouses, food depots, and other buildings where produce and other supplies are exposed to rat depredations have found that the cost of rat-proofing their buildings, even when the expense is considerable, is slight compared with the value of the resulting protection from loss, and that, in the long run, it is the cheapest rat insurance. Rat-proofing of buildings, wherever it can be accomplished at reasonable expenditure, is recommended as the best and most permanent means of rat riddance.

Natural Enemies of Rats—Cats that are of real value as ratters are rare. Ferrets are valuable only when handled by experienced men aided by good dogs. The use of dogs in killing rats is recommended wherever practicable—

small terriers, particularly when taught to hunt by themselves, are useful and sometimes will keep a farm free from rats.

Viruses—The control of rats by means of bacterial disease has a peculiar appeal that creates a ready market for the varied cultures already on the American market. This method, however, has proved generally unsatisfactory both in the experience of the Biological Survey and of other investigators and users, as gathered from reports from outside sources.

Community Coöperation—Organized anti-rat campaigns are increasing in popularity and are becoming the regular program not only in many municipalities and counties, but also in whole States. Such campaigns are of great value from economic, educational, and sanitary standpoints.

Assistance in planning, organizing, and prosecuting organized anti-rat campaigns will gladly be given by the Biological Survey Bureau of Agriculture, Washington, D. C., in the form of direct aid whenever practicable, by an expert for campaigns of large scope, or by furnishing plans, general instructions, publicity material, and sample posters.

Summary—Close all openings which provide entrance for rats, and screen basement windows in buildings that are otherwise rat-proof.

Insure greater cleanliness; promptly dispose of garbage and eliminate piles of trash and refuse.

Poison with barium carbonate on farms and dumps, in farm structures, warehouses, and other buildings, and, where considered advisable, in dwellings.

Trap systematically with common snap traps when the use of poison is inexpedient.

Fumigate burrows and keep efficient rat dogs to assist in reducing the infestation on farms.

Organize coöperative rat hunts and plan a definite and determined campaign of rat riddance.

CHAPTER CXVI

THE ATTITUDE THAT PHARMACISTS SHOULD HOLD TOWARDS VENEREAL DISEASE CONTROL AND THE ASSISTANCE THAT COULD BE RENDERED HEALTH AUTHORITIES

THE following statement was prepared by the Public Health Service of the United States:

1. Pharmacists should become fully acquainted with the pertinent laws and ordinances of the State, County, and City in which they practice, in so far as these relate to the dispensing of medicines and appliances, without a physician's prescription, for the treatment of venereal diseases, and also with reference to the sale of proprietary medicines and appliances for the same purpose. The observance of these laws by the pharmacist becomes a first consideration.

2. Pharmacists should prevail on persons applying to them for treatment to go to skilled physicians for the necessary advice and treatment and under no circumstances should they treat patients themselves.

3. The sale of appliances for the prevention of disease only, if construed to authorize the sale of disinfectants for the prevention of disease only, is a matter of particular concern for the reason that unless there are full instructions for the use of the disinfectants and unless the disinfectants have been thoroughly approved as efficient in the way in which the instructions indicate they should be used, it is likely that they would have very little if any value in preventing disease.

4. Pharmacists can best aid in the prevention of disease by referring all persons seeking advice or treatment to physicians, or to the city board of health if they are indigents. It should be kept in mind that these diseases may affect any part of the body, that blindness may result from acute infection of an adult's eyes, that syphilis is transmissible congenitally, and that inadequate and delayed treatment is the reason why so many lesions of the nervous system, the cardiovascular system, etc., develop and cause such great loss of earning capacity and so many disabilities.

CHAPTER CXVII

DISINFECTION

THE following is an abstract of an article by Thomas B. McClintic on disinfectants, their use and application in the prevention of communicable diseases.

The original was published as "Bulletin No. 42" of the Public Health Service and is reproduced by permission.

As is generally understood, disinfection is the destroying of disease-germs, thus rendering the organisms inert and harmless. Using the term in a broad sense it may be made, also, to include the destruction of disease-carrying insects, as the processes are usually carried out along the same general lines. The infective organisms of the communicable diseases are, with few exceptions, much more easily killed by disinfectants than are some of the common spore-bearing and highly resisting saprophytic bacteria usually present in all localities, but as nothing would be gained by carrying the operation to the extent of killing the latter class of non-pathogenic organisms, the process of disinfection is usually one of degree only; in other words, it is not necessarily carried to the point of complete sterilization. The specific germ of some of the infectious diseases, such as smallpox, scarlet fever, and measles, has not yet been positively demonstrated; nevertheless experience has proven that the infection of these diseases can be destroyed by the intelligent and proper use of disinfectants.

The question then naturally arises as to the best methods of accomplishing disinfection. The ideal disinfectant will in all probability never be found, and consequently there will always be encountered more or less antagonism against disinfection, for, as Rosenau aptly states, "the stress of modern activities demands disinfection processes that are instantaneous in their action, all pervading in their effect, cheap, harmless, and free from any unpleasant odors that might offend the senses of the fastidious. Such perfect disinfectants are unknown. It requires time, money, and the expenditure of well-directed and intelligent energy to accomplish satisfactory disinfection".

If the claims for some of the numerous proprietary disinfectants offered for sale upon the market were actually fulfilled, the process of disinfection would be very much simplified, but unfortunately this is not true, and in order to insure efficient results it is necessary to fall back upon the use of the old standard disinfectants that have stood the test of time and are known to be trustworthy. It should be borne in mind, too, that with the advance in medical science disinfection as intelligently applied today is far more specific than it formerly was and that the shotgun methods of former years have gradually passed into disfavor.

Without any pretense to originality, it will be endeavored to give here, in a simple and concise manner, the best methods of using disinfectants, and the special application of these methods in the eradication and prevention of some of the infectious diseases, with the hope that it may be of service, particularly to those more or less unfamiliar with the methods and technic of disinfection. The methods of disinfection, particularly the simpler ones, will first be described and then their special uses and applications will be given.

Disinfectants are usually divided into the following general classes:

(1) Physical agents, including sunlight, dry heat, burning, boiling, steaming, electricity, etc.

(2) Gaseous, including formaldehyde, sulphur dioxide, chlorine, etc.

(3) Chemical solutions, including bichloride of mercury, solution of formaldehyde, phenol (carbolic acid), tricresol, compound solution of cresol, potassium permanganate, lime, chlorinated lime, the hypochlorites, etc.

With the exception of heat, sulphur dioxide is the only one of the above-mentioned disinfectants that is used to any extent as an insecticide, while other substances used for this purpose are hydrocyanic acid gas, pyrethrum, petroleum, etc. As the uses of the physical agents, particularly the different forms of heat, are more or less familiar to all, they will not be further discussed in this paper, but the other disinfectants will be considered.

Gaseous Disinfectants

In determining the quantities of disinfectant substances to be used for gaseous disinfection, the cubic contents of the space to be disinfected is always estimated, and usually expressed in terms of a thousand cubic feet.

A room, each dimension of which is 10 feet, contains 1000 cubic feet, and the cubic contents of any space can be determined by multiplying together the length, width, and height, expressed in feet, which will give the contents in cubic feet.

To prevent the escape of the gas from the inclosure to be disinfected, fireplaces, ventilators, cracks of doors and windows, and other openings can be stuffed with cotton, paper, cloths, etc., but they are best closed by pasting them up, for which purpose strips of newspaper and a paste made from flour can be used.

All articles to be disinfected should be well exposed to the action of the disinfectant, as the penetrating powers of all gaseous disinfectants are more or less limited, therefore they should either be hung up or otherwise freely exposed to the gas.

Formaldehyde—For disinfection purposes formaldehyde gas is usually produced from the aqueous solution of the gas, the official (U. S. P.) name of which is "solution of formaldehyde". A commercial name for this solution is "formalin".

Solution of formaldehyde is supposed to contain 39 per cent of formaldehyde gas by volume, but from evaporation and deterioration it often falls short of this quantity, seldom containing more than 37 per cent of the gas. The gas, when used under favorable conditions, is one of the most powerful germicides at the disposal of the health officers. In addition to its germicidal efficiency it has the unique advantage over most other disinfectants in that it is not injurious to the ordinary household furnishings. Furniture, carpets, wall hangings, paintings, wearing apparel, and fabrics, with the possible exception of some of the very delicate anilin colors and polished steel, are unaffected by long exposures to the action of this gas.

It acts quickly as a germicide, but its powers of penetration are limited, so that it is necessary to have articles freely exposed in order to insure thorough disinfection. On account of lack of penetrating power it is evident that formaldehyde gas can not be depended upon to disinfect mattresses, upholstered furniture, or articles of that class requiring deep penetration; consequently after exposing them to formaldehyde gas they should be either burned, boiled, steamed (under pressure), or soaked in a disinfectant solution in order to make sure of destroying all possible infection.

Unfortunately the germicidal powers of formaldehyde are markedly affected by climatic conditions. With the temperature and humidity of the ordinary summer in the United States its efficiency as a surface disinfectant is unquestioned, but when the temperature is about or below 50° F., or the moisture in the atmosphere is below 60 per cent of saturation, the efficiency of formaldehyde is very much reduced. The temperature and humidity being below the points stated, polymerization of a portion of the formaldehyde takes place and its power of penetration, which at best is only slight, is still further diminished. These effects of low temperature and humidity may in part be overcome in room disinfection by artificial heating and at the same time boiling water in the room, by sprinkling the floors with water, and also by using an increased quantity of formaldehyde.

Formaldehyde gas is useless as an insecticide and is practically never used for that purpose. Flies and mosquitoes are killed by it only after a long exposure to the gas in concentrated form. It is non-toxic to the higher forms of animal life, including man, but produces in them an irritation of the respiratory, nasal, and ocular mucous membranes, thus causing coughing, sneezing, and "watering" of the eyes. Unless the exposure is prolonged these effects, however, are only temporary and pass off when no longer exposed to the gas.

Formerly formaldehyde gas was largely produced by means of generators, lamps, autoclaves, etc., methods requiring special apparatus and a certain amount of mechanical skill in operating, but those methods have now largely been supplanted by simpler ones which can be used in any household. In view of this fact the instrumental methods will not be dealt with in this paper, but the following methods of evolving the gas will be described:

(1) Formaldehyde-permanganate method.
(2) Formaldehyde-sheet-spraying method.
(3) Formaldehyde-aluminum sulphate-lime method.
(4) Paraformaldehyde.

Regardless of which method is used, everything should be in readiness before the disinfection process is started. All trunks and drawers should be opened and most of the contained articles hung up or otherwise exposed in the room, particularly if there is a possibility of their being infected. All cupboards, closets, and bookcases should be opened.

Fireplaces, ventilators, and cracks of doors and windows to be closed should, with the exception of the doors of exit, be closed before the disinfection process is started.

To get rid of the formaldehyde gas remaining after disinfection it is usually sufficient to open doors and windows and allow it to blow out. Ammonia was formerly used to a limited extent for neutralizing the gas, but, as it often causes a portion of it to precipitate in the form of a powder, which, when heated or moistened, will again give off a certain amount of formaldehyde gas, ammonia is now seldom used for that purpose. Even when the formaldehyde is allowed to blow out the odor of the gas is often perceptible for several days following disinfection. This, however, causes no trouble or inconvenience.

After disinfection with formaldehyde the quarters can usually be occupied an hour or two after opening the doors and windows.

Formaldehyde-Permanganate Method—When solution of formaldehyde is poured upon crystals of potassium permanganate a vigorous reaction takes place, accompanied by strong ebullition of the liquid and sufficient heat to produce a large quantity of formaldehyde gas, water vapor, etc. The time required for the reaction to begin, or at least to become apparent, varies from

a few seconds to a minute or two, depending upon the temperature. The reaction is apparently over in a few minutes and with proper proportions of substances the residue in the vessel is almost dry.

A convenient and efficient proportion to use is two parts of solution of formaldehyde to one part of permanganate, or in the proportion of a quart of the former to a pound (pint) of the latter. By using a greater proportion of permanganate than this, slightly more gas may be evolved, but in addition to requiring an increased expenditure of permanganate the danger of fire is also increased, as formaldehyde gas in a comparatively dry state is inflammable. The increased oxidation resulting from the additional permanganate is therefore more liable to cause combustion of the gas than when the proportions are used as just stated.

For mixing the solution of formaldehyde and permanganate a large galvanized-iron pail is very suitable. Pots or earthen vessels, usually being thick, are not as suitable as thin pails, on account of absorbing much heat from the reaction. The pail, though, may be heated before mixing the formaldehyde solution and the permanganate. On account of the vigorous ebullition during the reaction a 10-quart pail should be used for mixing 10 ounces of formaldehyde solution and 5 ounces of permanganate. Even then a few drops of the mixture may be thrown over, so that it is well to place the pail in a large tin pan or upon something to protect the carpet or floor. To prevent this sputtering over there is some advantage in using a pail with a flared top. As the process is attended with slight danger of fire, the reaction, which is quickly over, should be watched through a window or the pails placed upon a non-inflammable surface.

With this method the formaldehyde gas is evolved so quickly and in such a large volume that it is unnecessary, in houses with well-fitting doors and windows, to paste up cracks unless only a portion of the house is to be disinfected and the remainder is to continue to be occupied.

Closets, drawers, trunks, etc., should be opened, and when everything is in readiness the permanganate is placed in the pail and the formaldehyde solution poured over it. In disinfecting an entire house all inside communicating doors, halls, etc., should be opened and at least one pail placed in each room and hall, unless the rooms are very small. Large rooms may require more than one pail unless a pail proportionately large is used.

The quantity of formaldehyde solution and permanganate to be used per 1000 cubic feet of room space depends upon conditions. If the atmosphere is warm and humid 10 ounces of formaldehyde solution and 5 ounces of permanganate is sufficient, while if it is dry and cold double these quantities should be used. The pails should be placed about in the room or rooms as stated and the necessary quantity of permanganate weighed and placed in them; the formaldehyde solution for each pail should then be measured into a wide-mouthed cup or vessel and placed by the pail in which it is to be used. Do not use narrow-necked bottles or the pouring will require too much time. Although the reaction of formaldehyde solution with permanganate takes place quickly, by making preparations as advised one operator can "set off" a number of pails, there being nothing to do except to pour the formaldehyde solution over the permanganate. Of course the mixing should begin in the rooms most distant from the door of exit.

The time of exposure—that is, the time the premises should be kept closed—should be at least two and, preferably, four hours. At the end of this time the doors and windows are opened and the gas allowed to blow out.

Formaldehyde-sheet-spraying Method—This is a very simple and inexpensive method of evolving formaldehyde gas from formaldehyde solution and when properly used under favorable conditions is efficient. Formaldehyde solution, sheets, and a means of spraying the solution upon the sheets, are all that is required in the way of appliances. The sheets should be hung up over a cord or line and allowed to hang at an angle of about 45°, and it is of advantage, too, to slightly dampen them with water before hanging them up, as the formaldehyde solution will then be quickly absorbed and lessen its tendency to run off the sheets.

The formaldehyde solution should be evenly sprayed upon the sheets, which can be done with any spraying device, a very simple one being a flower watering pot provided with a sprinkler. The spraying should be done rather quickly, as the gas soon begins to be given off. The process should be carried out in each room. Not over 10 ounces of formaldehyde solution should be used for every 30 square feet of sheet surface. The area of a sheet is found by multiplying its length by its breadth.

This method is particularly applicable where a long exposure may be allowed, as the gas is gradually given off and the percentage of formaldehyde remains comparatively high during a relatively long time. This method should not be used at temperatures below 60° F., as the formaldehyde solution polymerizes on the sheets and very little gas is liberated. With fairly close-fitting doors and windows, pasting of cracks is unnecessary, unless a strong wind is blowing. However, large openings like fireplaces, openings into chimneys, ventilators, etc., should be closed either by pasting or with bunches of old rags.

As this method should be used only during warm months, 10 or 12 ounces of formaldehyde solution for each 1000 cubic feet of air space is sufficient.

The time of exposure should be from four to six hours. Open the doors and windows and, when possible, remove the sheets. The sheets are not injured in any way by the formaldehyde solution.

Formaldehyde-Aluminum Sulphate-Lime Method—In this method 2½ pounds of commercial aluminum sulphate are dissolved in 2 quarts of hot water and allowed to stand for a few hours. To 1 quart of this solution, 3 quarts of formaldehyde solution are added. To evolve formaldehyde gas from this latter solution it is poured over unslaked lime in the proportion of 10 ounces of the solution to 1 pound of lime. Just before using the lime it should be broken into small particles. It should slake easily in cold water. The lime should be placed in a pail or vessel and the solution poured over it. A few minutes after pouring the formaldehyde-aluminum-sulphate solution over the lime, the latter begins to slake and continues for 20 to 30 minutes during which time formaldehyde, steam, etc., are given off. The percentage of formaldehyde gas liberated by this method is relatively small as compared with the formaldehyde-permanganate method, but since a small quantity of formaldehyde is efficient when used under favorable climatic conditions this method will then give efficient results. This method, though, should *not* be used in cold, dry weather.

About 15 ounces of formaldehyde-aluminum sulphate solution, made as described above, and 1½ pounds of lime should be used for each 1000 cubic feet of air space. Cracks should be pasted up and fireplaces and ventilators closed, as the percentage of gas given off is relatively small. The time of exposure should be from four to six hours. The process should be carried out in each room.

This method of evolving formaldehyde gas has no advantages, but several

disadvantages, as compared with the formaldehyde-permanganate method, and is now seldom used. It is not as efficient as the sheet-spraying method.

Paraformaldehyde—Paraformaldehyde can be used, particularly for disinfecting small inclosures, under the same conditions of heat and moisture as already stated with regard to the other methods.

Paraformaldehyde is one of the polymeric forms of formaldehyde. It is a white powder and readily burns with a blue flame. For disinfecting purposes it should be heated to convert the paraformaldehyde into formaldehyde gas, but *under no condition* should it be allowed to burn, as the combustion destroys practically all of the formaldehyde. A good method of producing formaldehyde gas from paraformaldehyde is to place the paraformaldehyde in a metal utensil under which a lamp or alcohol flame can be placed. A special lamp or device can be obtained for the purpose, but an ordinary pint tin cup will suffice for heating therein an ounce or two of paraformaldehyde. The paraformaldehyde is placed in the cup and a flame applied underneath. The flame should not be too strong, for should the paraformaldehyde ignite no formaldehyde gas will be produced and there will be no disinfection. The space to be disinfected should be tightly closed and all cracks pasted up. For each 1000 cubic feet of air space two ounces of paraformaldehyde should be used. The time of exposure should be about four hours. If necessary, the flame under the utensil containing the paraformaldehyde can be left burning during the time of exposure.

A solution of paraformaldehyde can be made and used in the same manner that formaldehyde solution is used in the formaldehyde-permanganate method. For disinfecting 1000 cubic feet of space 2 ounces of paraformaldehyde are dissolved in 8 ounces of boiling water. This solution is then poured over 5 ounces of potassium permanganate contained in a 2-gallon pail, the details of procedure being the same as have been described for the formaldehyde-permanganate method.

There are many forms of candles and other preparations of paraformaldehyde made and sold upon the market for disinfection purposes, but bear in mind that any preparation of paraformaldehyde requiring that the preparation be ignited and burned in order to produce formaldehyde gas is useless for disinfection purposes, as the formaldehyde is destroyed by the combustion.

In using those preparations of paraformaldehyde that are heated to produce the gas, due allowance must be made for other ingredients than paraformaldehyde contained therein, and therefore a larger quantity should be used than when using pure paraformaldehyde, as at least 2 ounces of paraformaldehyde should be used for each 1000 cubic feet of space to be disinfected. For the reasons stated the use, for disinfection purposes, of proprietary preparations of unknown strengths should so far as possible be avoided.

Sulphur Dioxide—In the presence of moisture, sulphur dioxide is an efficient surface disinfectant. Its powers of penetration are limited and it will not kill spores, but when used under favorable conditions it will kill the contagion of most of the infectious diseases not due to spore-bearing organisms. Dry sulphur dioxide (SO_2) is practically without germicidal powers, but in the presence of moisture this gas is converted into sulphurous acid gas (SO_3) and sulphuric acid (H_2SO_4), upon which efficient disinfection with sulphur gas depends. While these converted products are destructive to germ life, they are also injurious to household furnishings, fabrics, etc., which is one of the greatest drawbacks to the use of sulphur gas as a disinfectant. These injurious effects and the feeble germicidal properties of the gas in the dry state, have greatly limited its uses, particularly in household disinfection, but it is still especially applicable for

destroying rats, flies, fleas, and other vermin that spread contagion, since it is highly fatal to animal life. It is, therefore, applicable and largely used for disinfecting holds of ships, stables, barns, granaries, freight cars, and structures of this character. Sulphur, either as flowers or in rolls or sticks, can usually be obtained at any drug or crossroads store.

In the presence of moisture sulphur dioxide attacks and causes oxidation of most of the metals, which, however, can be prevented by previously smearing petrolatum upon the exposed surfaces; it bleaches and injures cotton, linen, and woolen fabrics, curtains, etc.; it injures flour, except in the closed ("headed up") barrel; it softens paint and varnish, particularly if they have been recently applied; it injures soap, coffee, tea, sugar, rice, matches, etc., when they are freely exposed to it; it injures clocks; and it discolors wall paper if moisture is present.

The moisture necessary in destroying germ life with sulphur dioxide can usually be artificially produced without difficulty, as it can be added in the form of steam (sulphur furnace), and in the pot method it is automatically produced from the water in the pan in which the sulphur pot is placed. However, when using sulphur dioxide as a disinfectant in damp weather or in disinfecting holds of ships which are usually damp, the artificial production of moisture is unnecessary.

The inclosure to be disinfected with sulphur gas should be made as tight as possible, therefore the cracks of doors, windows, and keyholes should be pasted up; fireplaces, ventilators, radiators, and all openings should be tightly closed, either by pasting them up or in some other manner. This should all be done, except the door of exit, before starting the disinfection. For pasting, strips of paper and a paste made from flour can be used. After the disinfection is over, the pastings can be moistened with water and washed off. It is necessary, to avoid injury to the articles enumerated above, to remove them from the space to be disinfected. Brass or any metal furnishings are not injured, provided they are given a thin coating of petrolatum.

The principal methods of using sulphur dioxide are:

(1) The pot method.
(2) Liquid sulphur dioxide.
(3) Sulphur candles.
(4) Sulphur furnace (requiring special apparatus).

The Pot Method—This is the cheapest and simplest method of producing sulphur dioxide. The only materials required are pots, sulphur, and a small quantity of alcohol. Sulphur burns when liberally sprinkled with alcohol and lighted. It can also be started burning by placing a shovelful of hot coals of fire into it. As sulphur dioxide is produced by combustion of the sulphur, and as the combustion is dependent upon the available oxygen of the air, it will readily be seen that the rapidity of production of the sulphur gas will be governed by the area of the burning surface. It is therefore very important for rapid production that broad shallow pots be used.

Ordinary "Dutch ovens", iron buckets, etc., may be used, but the best pot for the purpose is one with a flat bottom, 12 to 18 inches in diameter, and with sides about 4 inches high. A dish pan answers the purpose very well.

Theoretically the complete combustion of 1 pound of sulphur in a space of 1000 cubic feet produces 1.15 per cent of sulphur dioxide, though 1 per cent is about what is produced in actual practice. Therefore, as 5 per cent is required to kill non-spore-bearing organisms, it is necessary to burn 5 pounds of sulphur for each 1000 cubic feet of space to be disinfected.

After estimating the cubic space to be disinfected the sulphur should be weighed, allowing 5 pounds for every 1000 cubic feet of space.

Sufficient pots should be available so that a depth of not more than 1½ to 2 inches of sulphur will have to be placed in each pot, although necessity sometimes requires a greater depth than this. The sulphur should be sloped toward the center so as to form a crater or depression in the center.

When using stick sulphur a portion of it should be pulverized or broken up. The pots should be distributed in the rooms to be disinfected according to the size of the rooms and number of pots. They may be placed upon the floor, tables, stoves, hearths, etc.

It should be borne in mind that the burning sulphur causes the pots to become very hot, and to avoid danger from fire it is necessary to place them upon objects not combustible or injured by heat. As already stated, this is best accomplished by placing them in pans containing an inch or two of water, as, besides the protection, the heat produces moisture from the water, which is necessary in sulphur disinfection. Pans not being available, the pots may be placed upon earthen or metal surfaces and efficient disinfection done, provided the atmosphere is reasonably damp. Theoretically, about 3 ounces of water should be volatilized for each pound of sulphur burned. The sprinkling of the sulphur with alcohol and lighting should not be done until everything is in readiness. A convenient and safe method of lighting the alcohol in the pots is to strike a match and before the head is entirely ignited to throw it into the pot. This will cause the alcohol to ignite. After lighting, the sulphur fumes do not begin to come off for a few minutes, so that one operator can start a number of pots. After lighting the pots, observe that they are all burning; then close the door of exit and paste up its cracks.

When the sulphur has been burning half an hour, search for sulphur fumes escaping from any openings that may have been overlooked and close them.

Leave the apartment or room closed for 12 hours, and then open doors, windows, etc., and allow the remaining sulphur fumes to blow out. It is well to have the windows so they can be opened from the outside, otherwise entrance to the rooms may be impossible for an hour or so. The rooms can usually be occupied in two or three hours after opening the doors and windows.

Liquid Sulphur Dioxide—The technic of disinfection with liquid sulphur dioxide differs from the pot method only in the manner of production, therefore that is the only phase of the subject that will be described here, the reader being referred to the description already given for further details.

The method has the advantage of liberating a large quantity of sulphur dioxide in a short time, but it is a far more expensive method than burning sulphur by the pot method, the relative cost being about 10 to 1. The method of using liquid sulphur dioxide, however, is very simple and it is free from any danger of fire. The liquid is prepared commercially and is usually obtained in metal cans or casks, which for use only require the simultaneous cutting of the leaden pipes on the tops of the necessary number of cans and the inversion of the latter in a metal or earthen vessel, when volatilization rapidly takes place.

To obtain the 5 per cent of sulphur dioxide required for disinfection, it is necessary to use 10 pounds of liquid sulphur dioxide for every 1000 cubic feet of air space. Therefore, the space should be estimated and the required quantity of liquid dioxide obtained. Of course, with this method the same preparations and precautions with regard to injury of certain articles should be carried out as with the pot method. If a number of adjoining rooms are to be disinfected, it is best to begin opening and inverting the cans in the most

distant rooms and work toward the door of exit. It is necessary to have everything in readiness and to work quickly as the gas is given off rapidly. If the container of the liquid dioxide is provided with a siphon or tube the liquid can be introduced by means of a tube through the keyhole into a suitable receptacle inside the room.

The time of exposure should be 12 hours.

One striking disadvantage of this method as compared with the pot method is that it produces no moisture, which is necessary to obtain the maximum disinfecting power of sulphur dioxide.

Sulphur Candles—As sulphur candles are applicable only for killing insects and not for disinfection purposes the method of using them will be described under sulphur as an insecticide.

Chlorine—Owing to its poisonous and destructive properties, chlorine is very seldom used as a disinfectant. Moisture is necessary for its action as a disinfectant, and in the presence of moisture it is also a powerful bleaching agent for all the organic pigments. Carpets, curtains, and fabrics generally are injured by its action. It is destructive to both animal and plant life. According to Rosenau the most convenient method of generating the gas is by decomposing 1½ pounds of chlorinated lime with 6 ounces of strong sulphuric acid. This produces sufficient gas for the disinfection of 1000 cubic feet of air space. Another method of generating chlorine gas is by adding four parts of strong hydrochloric acid to one part of manganese dioxide. For practical purposes of disinfection, according to Munson, free chlorine is much inferior to sulphur dioxide, since it is more difficult to control, more dangerous to manipulate, and more destructive in its effects.

Chemical Solutions

Bichloride of Mercury—This substance is also known as corrosive sublimate, bichloride, mercuric chloride, and corrosive mercuric chloride. In the pure state it is a white, crystalline substance and fairly soluble in water, thus differing from calomel (mercurous chloride), which is a white, amorphous powder and insoluble in water.

The "antiseptic tablets" or "bichloride tablets" sold on the market are usually composed of bichloride of mercury. These tablets are generally artificially colored (blue) in order to lessen the chances of accidental poisoning with them, as bichloride of mercury dissolved in water makes a perfectly clear solution (see poison tablets of corrosive mercuric chloride, page 500).

Bichloride of mercury is one of the most powerful germicides available. It has the disadvantages, however, of corroding metals, forming inert compounds with albuminous matter and of being very poisonous. It is therefore inadvisable to use it for disinfecting sputum, excreta, or under any condition in which it comes in contact with much albuminous or organic matter, since it forms inert compounds with these substances.

One part of bichloride of mercury will dissolve in 16 parts of cold water and in three parts of boiling water. The bichloride should be pulverized before attempting to dissolve it. Even then it dissolves with some difficulty. The solubility is increased by using sea water for the solution or by adding two parts per 1000 of sodium chloride (common salt) to the water employed. The water used should be free from organic matter and for dissolving the bichloride it is preferable that the water be hot.

The strength of solution used in disinfecting for the infectious diseases is usually 1 part of bichloride to 1000 parts of water, *viz*, a strength of 1 to

1000. This solution is made by dissolving 1 ounce of bichloride in 1000 ounces of water—approximately 8 gallons; a 1 to 500 solution is made by dissolving 1 ounce in 500 ounces of water, and so on for any other strength desired. The solutions are best made in an earthen or wooden vessel, a wash-tub or barrel being very suitable. The addition of a little indigo or other coloring matter will avoid the possibility of the solution being drunk by mistake.

To disinfect soiled clothing, bed linen, etc., they should be placed in a tub containing a 1 to 1000 solution and left for an hour. They can then safely be taken out and rinsed in water and laundered. Bichloride of mercury, however, is a mordant, and clothing containing stains, such as blood, etc., will be permanently stained if placed in bichloride solution. Eating utensils should not be placed in bichloride of mercury on account of the danger from poisoning. Infected floors, tables, wooden beds, chairs, walls, etc., can be washed with a 1 to 1000 solution of bichloride of mercury. For applying it, a floor mop may be used. Saturate the floors and other surfaces with the solution and allow them to dry. The hands and body, except the face, can be bathed in a 1 to 1000 solution without injury.

As already stated, feces, urine, sputum, and products containing albuminous matter should not be disinfected with bichloride solution unless no other disinfectant is available, in which case a 1 to 500 solution should be used.

Surgical instruments are corroded by bichloride solution and it should not be used for rendering them sterile.

"Antiseptic tablets" are usually very soluble in water, and the method of obtaining the desired strengths is stated on the label of the container. They are very useful when only a small quantity of bichloride solution is required. A 1 to 1000 solution is easily prepared from them and is very useful for washing the hands after handling the sick or any possible infected material. The hands should be bathed in the solution for two or five minutes after cleansing them with soap and water.

Solution of Formaldehyde—Solution of formaldehyde has already been considered under gaseous disinfection but it is also a valuable disinfectant solution. It has an advantage over bichloride of mercury in that its action is not retarded by albuminous matter; it is not corrosive; articles are usually not injured by it; it is a good deodorant; and it is not so highly poisonous as is bichloride of mercury.

Solution of formaldehyde is well adapted to the disinfection of urine, feces, sputum, and other discharges of like character, for in addition to disinfecting them, it also deodorizes them. For this purpose, according to Anderson, a 5 per cent solution of formaldehyde and one hour's exposure is required. They should be thoroughly mixed. Allowance must be made for the dilution caused by mixing the formaldehyde solution with the material to be disinfected. For instance, if 1 pint of feces is to be disinfected it should be mixed with 1 pint of a 10 per cent solution of formaldehyde, or a half pint of a 20 per cent solution, which in each case gives the 5 per cent strength required.

Solution of formaldehyde can not be used in the sickroom, as the liberated gas is irritating; nor is it adapted to the washing of floors, walls, etc., for the same reason.

Soiled linen and bedclothing can be disinfected by one hour's immersion in a 5 per cent solution of formaldehyde.

Disinfection with formaldehyde solution should be done out of doors, to avoid the irritating effects of the gas given off.

A few drops either of pure or diluted formaldehyde solution poured into water-closet bowls, urinals, sinks, etc., destroys offensive odors.

Phenol, Popularly Known as Carbolic Acid—This is a very useful disinfectant. It has a penetrating odor, a strong burning taste, and it is a corrosive poison. Pure phenol crystallizes and becomes solid at ordinary temperature, but it can be liquefied either by heat or by the addition of a small quantity of water, about 5 per cent.

Phenol is soluble in about 15 parts of cold water; that is, 1 ounce of phenol dissolves in 1 pint of water (16 ounces), which is about a 6 per cent solution.

Phenol dissolves in water with some difficulty. Therefore, to insure its solubility, hot water should be used and the mixture well agitated.

For disinfection purposes phenol is commonly used in solutions of 3 to 5 per cent. A 3 per cent solution is made by adding 3 volumes of phenol to 97 volumes of water; a 5 per cent solution is made by adding 5 volumes to 95 volumes of water, etc.

In these strengths phenol is not destructive to fabrics, colors, metals, etc. Therefore, it has a wide range of usefulness in disinfection. As it does not actively coagulate albuminous matter, it is useful for the disinfection of urine, feces, sputum, etc. For this purpose a 5 per cent solution is added to an equal volume of the excretions, the mass then thoroughly mixed and allowed to stand one hour before final disposal.

Soiled linen, bedclothes, etc., are best disinfected by immersion for one hour in a 3 per cent solution, and the same strength solution should be used for mopping floors, walls, etc. After handling the sick or any objects possibly infected, such as bedpans, sputum cups, etc., the hands may be disinfected by washing them for two to five minutes in a 2½ per cent (1 to 40) solution of phenol. The hands should then be washed or saturated with alcohol in order to avoid the benumbing effect of the phenol. As phenol does not kill spores it should not be used to destroy the infection of tetanus, anthrax, or malignant edema.

"Crude Carbolic Acid", or *"Tar Acid"* as sold upon the market, is a black, tarry liquid of very varying composition. It contains cresols and other compounds, but although some of these products have greater germicidal powers than pure phenol (carbolic acid), their solubility in water is so slight that the use of pure crude carbolic acid as a disinfectant is greatly limited. It is available, however, in soap solution in which form it is miscible in all proportions in water. It is official as the compound solution of cresol (see page 814) and is sold under various trade names such as *lysol*, *creolin*, etc., see page 815. Its uses are similar to phenol.

Potassium Permanganate—This is a germicide of undoubted power, but of very limited application in general practice on account of the readiness with which it is reduced and rendered inert by organic matter. Except in surgical practice its uses are largely limited to the disinfection of water tanks, cisterns, etc. For this purpose they are emptied of water and the interior thoroughly scrubbed with a 1 per cent aqueous solution of permanganate. After standing an hour or two they are washed out with water until the water comes away perfectly clear. Provided scrubbing of the tanks, etc., is impracticable, they may be filled with water and then enough of a strong solution of permanganate, made with boiling water, added to produce a dark rich purple color. After standing four hours, clean water should be added until the water in the tanks etc., comes away clear. The tanks are then ready for use. Potassium permanganate is soluble in 16 parts of cold and 2 parts of boiling water. Stains produced by permanganate can be removed by washing in a solution of oxalic acid, lime juice, or vinegar.

Lime—This substance is also known as *quicklime* and calcium oxide. It is cheap and when used properly is an efficient disinfectant. Lime may be used for the disinfection of feces, urine, sputum, and other dejecta; it is useful for the disinfection of privies and for any condition under which the soil is suspected of being infected, as in cellars, mucky back yards, etc., and it is also useful, when applied as whitewash, for the disinfection and sweetening of cisterns, cellars, barracks, barns, stables, poultry houses, etc.

It is necessary that the lime be obtained fresh and kept in the unslaked condition. As unslaked lime is often in large, stony masses, it should be sufficiently slaked by the addition of a little water to enable its being distributed for disinfection purposes. In then applying it there should be present only enough moisture to cause the slaking to be completed. This necessary moisture is present in urine, feces, sputum, etc., and is usually present in damp cellars, cisterns, privies, dairies, and back yards, it being required only that these localities be liberally sprinkled with the lime. For disinfecting feces, sputum, etc., they should be well mixed with an equal quantity of lime and allowed to stand for an hour or so before final disposal.

Air-slaked lime is practically inert as a disinfectant; therefore, care should be exercised to keep the lime from the air as much as possible before using it.

Milk of lime is a better disinfectant than lime. It is made by mixing, in a tub or bucket, fresh lime with four times its volume of water, the resulting mixture being ready for use. It is useful for disinfecting excreta, etc., to which it should be added in equal volume and allowed to stand for two hours before final disposal. Milk of lime is most powerful when first prepared. It therefore should be made and used fresh, unless it can be bottled or in some way protected from the air after it is prepared.

Chlorinated Lime—Chlorinated lime, or bleaching powder, popularly miscalled "chloride of lime", according to Rosenau, ranks with unslaked lime in power and value as a germicide, and has about the same uses in practical disinfection. It is a much better deodorant than lime.

As chlorinated lime deteriorates on exposure to the air, through the liberation of its chlorine, it should be kept in air-tight containers and preferably stored in a cool, dry place.

For disinfection purposes it may be used either as a powder or in solution. As a powder, it is applied in very much the same manner as lime. Cellars, privies, etc., are simply sprinkled with it, but not so liberally as when lime is used. It should be well mixed with urine, feces, sputum, etc., in sufficient quantity to form about 4 per cent of the entire mass.

Small quantities of chlorinated lime sprinkled in sinks, urinals, water-closet bowls, etc., will destroy foul odors.

By mixing 1 pound of good chlorinated lime with 4 gallons of water a *solution of chlorinated lime* is obtained which is very useful for disinfection purposes. With this solution floors may be mopped and the hands disinfected by washing them in it for a few minutes. Excreta and sputum are disinfected by thoroughly mixing them with equal volumes of this solution and allowing to stand for one hour.

Chlorinated lime corrodes metals, but the injury to agate ware, such as bedpans, is only slight. It bleaches and otherwise injures fabrics. The disagreeable odor resulting from the use of chlorinated lime in the sickroom may be removed by hanging about in the room towels saturated with a strong solution of baking soda (see also page 568).

The Hypochlorites—As the active disinfection agent found in solutions of chlorinated lime is principally calcium hypochlorite, the uses of the hypochlorites are practically the same as the solution of chlorinated lime.

Labarraque's solution is an aqueous solution of several chlorine compounds of sodium, chiefly sodium hypochlorite and sodium chloride.

It may be diluted with twice its volume of water and used for the same purposes and in the same manner as the solution of chlorinated lime.

Other hypochlorites and chlorine compounds were largely developed during the World War for the disinfection of wounds and also for destroying bacteria in drinking water. These are discussed on pages 546 and 570.

The Practical Application and Use of Disinfectants and Insecticides in the Eradication and Prevention of Communicable Diseases

There are already a large number of diseases known to be communicable, and the list is still increasing as time goes on and new discoveries are made.

As communicable diseases are preventable, this, then, is the day of preventive medicine, and a large share of the responsibility naturally falls upon the medical profession, particularly the health authorities. Their work, however, would be very much handicapped and often go for naught without the aid of the general public; therefore it must do its part, and its part is no small one.

A knowledge of medicine is not always necessary in order to conform to the simple rules of hygiene and intelligently to apply the use of disinfectants in the prevention of communicable diseases. "Communicable", "infectious", and "contagious" are terms that have become more or less synonymous in their meaning, and are often used interchangeably to convey the same idea in referring to the transmission of disease.

A thorough understanding—which at present is lacking—as to the exact nature of the cause and methods of transmission of some of the communicable diseases might make it possible to inaugurate for their prevention more effective and probably simpler methods than those at present in use.

In the case of many of the communicable diseases, however, the specific organism is known and its modes of transmission are understood; with others the specific germ is known, but its modes of transmission are not at all or only poorly understood; with others the organism has not been identified, but its modes of transmission are at least fairly well understood; while with still others the specific organism or cause is still unknown and its ways of transmission are only vaguely understood. Furthermore, some of the communicable diseases are transmitted through the agency of insects acting as simple carriers of the infection; others through insects as intermediate hosts; and others through food, drink, contamination of the air, contact, and various other ways.

It is evident that the uses and application of disinfectants and insecticides in the prevention of all the communicable diseases is a large subject, and to take up each disease in detail would reach far beyond the limits of this article. Therefore, as some diseases call for the same general hygienic management and preventive measures, the one most typical of the class will be described, and the remaining ones of that class described only in so far as they may differ from the one described as typical. For instance, the prophylactic measures that should be carried out against typhoid fever are very much like those that should be used against cholera, dysentery, etc., and, therefore, typhoid will be taken as typical of the class; likewise smallpox will be described

as typical of the exanthemata, others of which are scarlet fever, measles, chicken pox, etc.

It should be borne in mind that, after all, disinfection is a more or less relative process and that it can but seldom be made absolute, particularly in so far as the infection of the communicable diseases is concerned. Patients suffering with some of the communicable diseases are constantly eliminating the infection from their systems and to disinfect all the infection thus eliminated is well nigh impossible. Nevertheless, most of it can be destroyed by the intelligent use of disinfectants, thus reducing to a minimum the danger of the infection being spread.

Typhoid Fever—Typhoid fever is a communicable disease caused by the *Bacillus typhosus*, a germ so small that it can not be seen except with a microscope.

The germs are contained in enormous numbers in the feces, usually in the urine, and often in the sputum of typhoid patients. Typhoid fever is always contracted by taking these germs into the body, through the mouth, either with the food, drink, or otherwise.

A small particle of typhoid excreta, even what will adhere to the legs of a fly, may contain the typhoid organism in large numbers. It is easy then to understand how flies and other insects may spread typhoid infection. They light upon the feces, urine, sputum, or even the lips of the patient; they then may infect food and drink by lighting upon it, or they may carry the infection direct to healthy persons.

The fly, therefore, should be rigidly excluded from the sickroom and from the whole house, if possible, by screening; fly paper or fly poison should be exposed in the sickroom to kill any that may by chance gain entrance thereto. During certain seasons of the year the fly may not be present, but under no condition should excreta of typhoid patients be exposed to flies, at least until it has been thoroughly disinfected. The disinfection should, therefore, be done in a fly-proof inclosure.

The sickroom should have a bare floor, so that it may be washed with a disinfectant from time to time and whenever it may be soiled with the patient's excretions; unnecessary furniture should be excluded from the room; a basin containing a 1 to 40 solution of phenol or a 1 to 1000 solution of mercuric chloride should be in readiness for the doctor's and nurse's hands. A cup or glass containing a 1 to 40 solution of phenol for the thermometer should be on hand, and the thermometer should be kept entirely submerged in the solution when not in use; one or more bedpans should be available, and there should be on hand a supply of disinfectants, as well as some buckets or vessels in which to prepare the disinfectant solutions.

Special gowns for those attending the patient may be used, but they are not necessary, provided intelligent care is exercised. The nurse, however, should wear a rubber apron when bathing the patient, and it should be frequently washed in 3 per cent phenol solution. Visitors and others not required in the sickroom should be excluded.

Disinfection and Disposal of Excreta—Feces, urine, sputum, and all discharges from a typhoid-fever patient should be disinfected as soon as they leave the patient.

This is economically and efficiently accomplished by having a jar, bucket, or pan large enough to hold several times the volume of the excretions voided in 24 hours. It is placed convenient to, but not in the sickroom, and not accessible to flies. The urine, feces, etc., are placed in it when they are

voided, and a volume, equal to, or greater than the volume of excretions, added to it of one of the following solutions:

Solution of chlorinated soda (page 569).
Milk of lime (page 672).
Solution of phenol, 5 per cent.
Solution of formaldehyde, 10 per cent.

The bedpan is rinsed with the disinfectant solution and it then should be immersed for 10 minutes in one of the above solutions, contained in a suitable vessel, as it must be remembered that the outside of the bedpan may be infected by coming in contact with the patient. Bedpans may also be disinfected by sprinkling them with a strong solution of formaldehyde and then simply covering them with a heavy cloth for 15 to 20 minutes. On account of the formaldehyde gas given off this will have to be done out of doors.

In the above manner the entire excretions of a patient for a day can be disinfected and disposed of in sewers, water-closets, privies, etc., without danger of spreading the infection.

Chlorinated lime (powdered form), if used for disinfecting excreta, should be thoroughly mixed with the excretions in sufficient quantity to form 4 or 5 per cent of the entire mass. Likewise, lime used for the same purpose should be added in volume equal to that of the excretions.

When it is impracticable to disinfect the excretions for 24 hours, as stated above, bear in mind that excretions from typhoid patients should not be finally disposed of until they have been exposed to the action of the disinfectant for at least one hour, and under no condition should the excretions be disposed of without disinfection.

The typhoid germ is rather easily killed by heat; therefore in rural districts when disinfectants are not available or only in very small quantities, typhoid excreta can be disinfected with boiling water. In this case the excretions may be sufficiently disinfected to render them safe by filling the bedpan containing the excretions with actually boiling water and allowing it to stand until cool; the contents of the pan are then disposed of, preferably by burying, and the pan rinsed (scalded) with boiling water. Of course the excretions may be disinfected by boiling them in a vessel located in the back yard or some other suitable place. The bedpan though, after it is emptied, should be placed in boiling water for a few minutes.

The preventive measures outlined above should be kept in force, with regard to the urine and feces of typhoid patients, for two or three weeks after recovery, as these excretions may contain the typhoid organism for a considerable time after convalescence. Typhoid excretions should *never* be disposed of where they may get into the water supply, even though they have been disinfected.

Disinfection of the Hands—After handling the patient, bedpan, soiled linen, or any possibly infected material, the hands should be washed for at least two minutes in one of the following solutions:

Bichloride of mercury	1 to 1000
Phenol (carbolic acid)	1 to 40
Compound solution of cresol, or lysol	1 to 100

After washing the hands in any one of the last two solutions they should be rinsed in alcohol to avoid the benumbing effect of these solutions. Persons engaged in handling and managing typhoid-fever patients should avoid, as far as possible, placing their hands about their own faces, and they should

invariably wash their hands in one of the above disinfectant solutions before eating their meals.

Disinfection of Soiled Linen, Bedclothing, Eating Utensils, etc.—Soiled linen, towels, bedclothes, etc., are best disinfected by boiling them for a few minutes. They may also be disinfected by one hour's immersion in a 3 per cent solution of phenol or a 1 per cent solution of cresol, etc.

Eating and drinking utensils, after being used by the patient, should be washed in boiling water. They should not be used by others, at least until they have been sterilized by boiling.

Disinfection of the Bath Water—The water used in bathing the patient may undoubtedly be infected by the patient's excretions. The ordinary bath of 50 gallons of water may be disinfected by mixing in it half a pound of chlorinated lime and allowing it to stand for half an hour before disposing of it.

Terminal Disinfection—Gaseous disinfection of the room after convalescence, death, or removal of the patient is not always necessary, but it is advised as a measure of safety against any possible infection that otherwise might escape disinfection. It is therefore recommended that formaldehyde gas be used, as described on page 1866.

The floor, walls, tables, bed, chairs, etc., should be washed with a disinfectant solution, particularly if gaseous disinfection is omitted. The bedclothing, pillows, linen, etc., should be treated as already described. Without the use of a steam chamber the disinfection of mattresses is a difficult and uncertain problem. Therefore, it is far better that they be burned.

It may be well to state here that during the prevalence of typhoid fever in a house or community it is well to drink only boiled water, and either to avoid drinking milk or drink it only after it has been heated to the boiling point.

Bear in mind, then, that the watchword in typhoid-fever prevention is to *disinfect the excretions as they leave the patient, and to avoid taking living typhoid germs into the body in the food, drink, or otherwise, for without taking these germs into the body through the mouth there will be no typhoid fever.*

Cholera—Cholera is a communicable disease due to the *Vibrio choleræ asiaticæ* or, as it is often called, the "comma bacillus". The disease is sometimes called Asiatic cholera, on account of its home in India, and to distinguish it from *cholera nostras, cholera morbus,* and other forms of non-communicable affections with choleraic symptoms.

The feces always, and the vomit frequently, of those having the disease contain the germ in great numbers. They, however, are not found in the urine.

The germs are conveyed from sick to healthy persons and the disease thus contracted in almost the identical way as is typhoid fever. The reader is therefore referred to the description of typhoid fever given above for the details of disinfection and other preventive measures to be carried out against cholera.

Dysentery—Dysentery is a communicable disease occurring in epidemic form, especially in the tropics or during the hot season of the year. It is sometimes called "epidemic dysentery" to distinguish it from "amebic dysentery". Dysentery is caused by the *Bacillus dysenteriæ*, a minute bacterial organism, while amebic dysentery is believed to be due to the *Entamœba histolytica*, an organism belonging to the animal kingdom and rather resembling in appearance a white blood cell. The former, then, is due to a bacterium, the latter to a protozoön. The two diseases, however, are contracted in very much the same manner, namely, by taking the organisms into the body through the mouth, usually with the food and drink.

The feces of patients having either one of these diseases contains the specific organism in large numbers. Therefore what has been stated with regard to the prevention of typhoid fever applies also to the prevention of both dysentery and amebic dysentery.

Smallpox—Smallpox is highly communicable, but the cause of the disease has not been discovered. The disease is often referred to as "contagious" because it is readily conveyed by contact between the sick and the well. The exact manner in which the virus of infection of smallpox is given off from the body of the patient is not definitely known, but it is thought to be thrown off from the body of the patient into the surrounding air, perhaps with the exhaled breath and certainly from the eruption, whether fluid or dried in the crusts.

The infection of smallpox is thought to enter the body through the respiratory tract.

The preventive measures to be carried out against smallpox are, briefly stated, *vaccination, isolation,* and *disinfection.*

Vaccination—All persons should be vaccinated at least by the time they are a year old. If the vaccination does not "take" it should be repeated until it does "take". They should be vaccinated again about every five years or whenever they are exposed to smallpox. Persons continuously exposed to smallpox should be vaccinated at least once a year.

Isolation—Whenever possible, smallpox should be treated in an isolation hospital provided for contagious diseases. Where this is not practicable, a room should be used that is isolated as much as possible from the remainder of the building. The room, before being occupied by the patient, should be divested of all unnecessary furniture, hangings, draperies, carpets, etc. It should be capable of being darkened and freely ventilated. An adjoining room should be available for the use of the doctor and nurses, as well as for disinfection and other obvious purposes. There should be no communication with the patient except on the part of the necessary attendants, nurses, and the physician.

Disinfection—Body clothing worn by the patient before taking to bed should be boiled or burned. All linen, garments, towels, etc., soiled or used by the patient should, as soon as they leave the patient, be immersed at least one hour in one of the following solutions:

Phenol (carbolic acid)	5 per cent.
Compound solution of cresol, or lysol	1 to 2 per cent.
Chlorinated lime	4 ounces to 1 gallon of water.

As a further measure of safety they should then be boiled, after which they may be laundered and again used, if desired.

Handkerchiefs or clothes soiled by secretions from the patient's nose and mouth had better be burned, though they may be disinfected, as stated above.

The urine and feces of smallpox patients are not supposed to contain the virus of smallpox, but since they may become infected either during or after they are passed by the patient they should be disinfected before disposing of them. They may be disinfected in any one of the ways described for the disinfection of typhoid excreta.

Eating utensils, medicine glasses, etc., used by the patient should be immersed in actually boiling water. Food that has been in the sickroom, but not consumed, should either be burned or placed in boiling water. All disinfection should, so far as possible, be done in a room adjoining the sickroom

or, if that is not available, in the sickroom. The doctor or others temporarily entering the sickroom should wear gowns provided for the purpose.

The nurse should wear dresses of material not injured by disinfectants, for these garments, as well as the doctor's gowns, should be disinfected.

The physician, nurses, etc., after being with the patient, should change their clothing before mingling with other persons. After handling the patient or any possibly infected material, the hands of the operator should be washed for a few minutes in phenol solution 1 to 40, bichloride of mercury 1 to 1000, or some other disinfectant solution. The floor of the sickroom should occasionally be dampened with one of these solutions.

In cleaning the sickroom the raising of dust should be guarded against by using a damp cloth or mop for the purpose, or by dampening the floor before sweeping it.

By applying a bland oil, such as petrolatum, to the surface of the skin of the patient during the stage of desquamation, the dissemination of the exfoliated particles of skin, crusts, etc., may be largely prevented.

Remember that smallpox is infective during the entire period of desquamation and that the patient should be treated accordingly. When the patient is able to be up and desquamation is fairly well along, the body of the patient may be sponged daily with a 1 to 2000 solution of bichloride of mercury. The patient should then occupy another room, at least until the original sickroom can be disinfected. To do this, everything in the room should be left *in situ* and formaldehyde gas applied by one of the methods already described, preferably by the formaldehyde-permanganate method. In rural districts, if formaldehyde is not available, sulphur dioxide (pot method) may be used as described on page 1871. Sulphur dioxide, however, is rather difficult to confine to one room.

After the gaseous disinfection is completed the floor, tables, chairs, etc., should be washed with a 3 per cent solution of phenol or some other disinfectant solution. The mattress should be burned and the bed linen, garments, and other articles in the room disinfected, as has already been stated.

Any room that may be occupied by the patient during the stage of desquamation should, when vacated, be disinfected in accordance with the rules that have been outlined above.

When the stage of desquamation is entirely over—that is, when the skin is smooth and scales or particles of skin are no longer being given off, even from the pocks of the scalp—the entire house should be disinfected with formaldehyde gas.

After the disinfection is over the room last occupied by the patient should be further treated, as has been stated.

Of course, if the patient dies or is sent to a hospital, the room and entire house from which the patient is removed should be thoroughly disinfected in accordance with the rules outlined to be carried out after the patient's recovery.

Scarlet Fever—Scarlet fever is a highly communicable disease, but the nature of the specific organism or cause is not yet known. The infection is likely contained in the secretions of the nose and mouth, and certainly in the exfoliated particles of skin. Desquamation is often so extensive in this disease that it amounts almost to a complete peeling of the outer layers of the skin. The infection seems to live more or less indefinitely in the exfoliated particles of skin, and the disease is often in this way conveyed from the sick to healthy persons.

Scarlet fever is very analogous to smallpox from the standpoint of con-

veyance, prophylaxis, etc. Therefore, omitting the subject of vaccination, what has been outlined with regard to preventive measures, management, disinfection, etc., for smallpox applies almost equally well to scarlet fever. The reader is consequently referred to the subject of smallpox for many of the details omitted here.

The patient should be isolated in a similar manner and the same precautions taken as have been stated for smallpox. All soiled linen, towels, bedclothes, etc., eating utensils, urine, feces, sputum, and nasal secretions should be disinfected; and the same care of the hands and of the floor, the same precautions as to the doctor's gowns and the nurse's wearing apparel should be taken as have been already outlined above for smallpox.

Remember that it is during the desquamatory or peeling stage of scarlet fever that the disease is most dangerously communicable, and that this condition exists until the stage of desquamation is entirely completed. During this stage the body of the patient should be daily sponged with a 1 to 100 phenol or a 1 to 2000 bichloride solution. In children, however, the use of phenol solution is not entirely free from danger.

Disinfection of the room, bedding, etc., during the stage of desquamation, and disinfection of the entire building, room, and bedding, etc., after desquamation is over should be carried out as in the case of smallpox.

The floor of the sickroom should not be swept in a manner that will raise the dust, as the infection may thus be spread. Either dampen the floor or use a damp mop or cloth for cleaning it.

Measles—Measles is a communicable disease the cause of which is unknown. It usually occurs in epidemic form. The infection is present in the secretions and in the skin, and there seems to be no doubt but that it is present in the secretions of the nose and mouth very early in the disease.

Direct contagion is common, but dried particles of skin, sputum and nasal secretion containing the infection may be conveyed in dust, clothing, etc., and thus spread the disease. Measles is, therefore, spread in very much the same manner as smallpox and scarlet fever. Consequently the disinfection for measles is the same as that described for smallpox, to which the reader is referred.

Attention is called to the fact that measles being a very common disease, it is not often deemed necessary to take the precautions of isolation and disinfection for measles that are taken for smallpox and scarlet fever; but it should be borne in mind that in the United States measles caused more than twice the number of deaths caused by smallpox in the same length of time.

Chicken Pox—The cause of chicken pox is unknown, but it is undoubtedly due to a specific infection.

The disease is highly "contagious" in the same sense that smallpox is, *viz.*, by contact between the sick and the well. The disease is spread in much the same way and through about the same channels that smallpox spreads, and therefore the same disinfection measures that apply to smallpox apply also to chicken pox.

Erysipelas—Erysipelas is communicable and is caused by the *Streptococcus erysipelatis*. The organism is contained in the pus and secretions from the seat of the inflammation, and also in the desquamating skin of those suffering with erysipelas.

It is not definitely known how the infection enters the system, but probably it is through the abraded skin or mucous membranes; at least, persons with wounds or abrasions of the skin are very susceptible to infection with erysipelas.

Patients suffering with erysipelas should be isolated and the disinfection

measures for erysipelas carried out along the same general lines as have already been prescribed for scarlet fever.

Diphtheria—Diphtheria is a communicable disease caused by the *Bacillus diphtheriæ*. The germ is found in the secretions of the mouth, nose, and throat, and in the membrane from the site of the lesion in diphtheria. It may sometimes be found in the throats of persons showing no signs of the disease. It is not found in the air unless particles of secretions, membranes, etc., after drying, are blown about with the dust. The infection may be directly communicated from mouth to mouth by kissing, coughing, etc., or indirectly by objects that have become contaminated with the germs of the disease. It may also be spread by food, especially milk.

The uses of antitoxin in the prophylaxis and treatment of diphtheria will not be discussed.

Isolation—Isolation of diphtheria should be carried out as prescribed for smallpox.

Disinfection—The germ being contained in the secretions of the nose, mouth, and throat, it is obvious that these secretions should be disinfected as soon as eliminated, and that cloths, handkerchiefs, etc., used to receive them should be disinfected or burned. Bed and body linen of the patient, when removed or soiled, should be immersed for one hour in one of the following solutions: Phenol, 5 per cent; formaldehyde, 5 per cent; and compound solution of cresol or lysol, 2 per cent. The immersion in the formaldehyde solution can not be done in the sickroom. Eating utensils, medicine glasses, etc., used by the patient should be disinfected in boiling water. The thermometer, except when in use, should be kept in a 3 per cent solution of phenol. Brushes, swabs, etc., used about the patient's mouth should, when not in use, be kept in a weak (1 per cent) phenol solution, and when no longer required they should be burned.

Before disposing of feces or urine, they should have added to them, and allowed to stand for at least an hour, an equal volume of one of the following: A 5 per cent solution of phenol, or a solution of chlorinated lime, 4 ounces to the gallon of water.

The hands of attendants, after handling the patient or any material connected therewith, should be washed in a 1 to 40 solution of phenol or a 1 to 1000 solution of bichloride of mercury.

Upon convalescence of the patient the entire house should be disinfected with formaldehyde gas, preferably by the formaldehyde-permanganate method. The room in which the patient was sick should then be washed with a disinfectant solution, the mattress burned, and the bedding, etc., either disinfected as described above or boiled or burned.

The *Bacillus diphtheriæ* often exists in the throat for some time after convalescence; therefore, the patient should be kept isolated until bacteriological examinations no longer show the presence of the diphtheria organisms in the throat.

Epidemic Cerebrospinal Meningitis—This is a communicable disease caused by the *Diplococcus intracellularis meningitidis*. The organism is found in the cerebrospinal fluid and in the nasal secretions. It is possible that it is sometimes contained in the sputum, urine, and feces.

The methods of conveyance of epidemic cerebrospinal meningitis are not yet definitely settled, but it seems very likely that it and diphtheria are communicated in very much the same way. The measures of isolation, disinfection, etc., prescribed above for diphtheria apply and should be enforced against meningitis.

Acute Anterior Poliomyelitis—This disease is also known as "epidemic poliomyelitis" and "infantile paralysis". The cause of the disease is unknown, and it has been definitely proven to be a communicable disease. It may occur in epidemic form. The infection is undoubtedly contained in the nasal secretion and probably in the sputum, urine, and feces of those having the disease.

The way in which the infection is communicated from sick to healthy persons is not well established, but it probably takes place in much the same manner as in the case of diphtheria and epidemic cerebrospinal meningitis; and therefore the same preventive measures should be rigidly carried out against it that have been prescribed for the two latter named diseases.

Influenza—Influenza is a highly communicable disease, occurring in widespread epidemics and caused by the *Bacillus influenzæ*. The organism is found in great numbers in the secretions of the nose and mouth of those suffering with the disease. The preventive measures for influenza should be carried out along the same lines as those prescribed for diphtheria.

Pneumonia—Pneumonia, croupous or lobar pneumonia, is a communicable disease. It is caused by the *Diplococcus pneumoniæ*. The organism is widespread and is often found in the sputum of healthy persons. The sputum and nasal secretions of those suffering with the disease contain the organism in enormous numbers. It is therefore obvious that the disease may be communicated in very much the same way that diphtheria is communicated, and that, from a prophylactic standpoint, it should be handled accordingly.

Tuberculosis—Tuberculosis is a communicable disease prevalent in all parts of the world.

It is caused by the *Bacillus tuberculosis*, a very minute organism or bacterium. Tuberculosis may affect any part of the human body, although the lungs and respiratory tract are the parts most frequently affected, in which case the disease is often called "pulmonary tuberculosis", "consumption", etc. This is the variety of the disease that is the most dangerously communicable and therefore the one that will be especially considered here.

The bacillus of tuberculosis is usually contained in the sputum of consumptives in large numbers. It is very often contained in the nasal secretion and feces and sometimes in the urine. The germs of tuberculosis outside the body are long-lived and resistant to destruction. It is obvious, then, that the germs may be scattered far and wide by the constant coughing and spitting attending consumption. The dried secretions containing the organisms may mix with the air and dust and thus be inhaled into the lungs of healthy persons.

The germs may also be communicated in many other ways, as, for instance, in the common use by healthy persons and consumptives of drinking cups or glasses, towels, tableware, soap, eating utensils, beds, berths, etc.; from mouth to mouth by kissing or coughing; through the food, especially milk and meat from tuberculous animals; and by the association or living of healthy persons with consumptives. It is largely by means of the sputum in the moist condition that a consumptive infects another person.

Isolation—A consumptive should be isolated, though not necessarily in the strict meaning of the term as applied to smallpox or scarlet fever. The patient should sleep alone, whether it be in a room, a tent, or in the open. If a room is used, it should be one that is isolated as much as possible from the remainder of the building. It should preferably be on the sunny side of the house and well ventilated. Consumptives that are able to be up and around should spend their time, as far as possible, in the open air, but when indoors

they should occupy their own rooms. The consumptive's room should be frequented only by those having duties to perform therein.

Disinfection—Be careful to *destroy all the sputum of consumptives.*

The germ of tuberculosis is easily killed by heat, but it is rather difficult to kill it with chemical disinfectants, especially when it is incorporated with sputum. Therefore the sputum from a consumptive should, as far as possible, either be burned or boiled.

Portable spit cups that are destructible and cheap should be used by consumptives, and after a cup has been in use a few hours it should be burned. If indestructible cups are used, they should contain, while in use, a small quantity of a 5 per cent solution of phenol or a solution of chlorinated lime, and they should be disinfected each day by boiling them and their contents in water. The same measures should be carried out with regard to spittoons, whether they are used by the consumptive or by the public. The spitting in public spittoons by consumptives should be prohibited, but as a matter of fact it often occurs. Consumptives should expectorate only into their own private cups or into the fire. During the act of coughing consumptives should hold a handkerchief before the mouth in order to catch the particles of sputum expelled.

Napkins, handkerchiefs, clothes, etc., used by consumptives should be disinfected in boiling water. Eating utensils, drinking cups, medicine glasses, etc., should also be disinfected in actually boiling water, and under no conditions should they be used by healthy persons until they have been disinfected. Consumptives should never use public drinking cups.

Bed and body linen removed or soiled by the consumptive should be placed directly into a kettle of water and boiled; if this is not practicable at the time of removal they should be placed in a 5 per cent solution of phenol or a 2 per cent compound solution of cresol or lysol until such time as they can be boiled.

As the feces of consumptives usually contain the germs of tuberculosis in large numbers, the fecal discharges of consumptives should be disinfected in accordance with the same general rules as have been prescribed for the stools in typhoid fever.

The floor of a consumptive's room should occasionally be mopped with a disinfectant solution. The floor should *never* be swept without guarding against the raising of dust; either dampen the floor before it is swept or use damp mops or cloths for cleaning it.

Consumptives, when not confined to the bed, should occasionally wash their hands in a disinfectant solution, such as 2.5 per cent phenol or 1 per cent compound solution of cresol or lysol. After handling a consumptive or any infected material the hands of the attendant should be washed in one of the solutions just mentioned.

Upon the permanent vacation of the quarters occupied by a consumptive, whether through death, removal, or recovery, the room, and preferably the entire building, should be disinfected with formaldehyde gas, as described on page 1866. The ingredients for producing the gas not being available, sulphur dioxide (pot method) should be used. The treatment of the room, bedding, etc., following the gaseous disinfection should be as has been prescribed for smallpox.

Leprosy—Leprosy is a communicable disease caused by the *Bacillus lepræ.* It is not as highly communicable as tuberculosis, but in many other ways the two diseases are very analogous. The germs of leprosy are contained in the lesions of leprosy in enormous numbers, and therefore they are

being continually thrown off with the scales, discharges, etc., from the lesions of those suffering with the disease. The nasal secretions of lepers usually contain the germs in large numbers, and consequently many of them are eliminated from the body in these secretions.

The way in which the disease is communicated from the leper to the non-leper is not well understood, but it has been observed that a non-leper sometimes contracts the disease after having lived or associated with a leper.

There is no doubt that lepers should be segregated, but ample provision should be made for their maintenance and comfort. The same thing, said of tuberculosis, would undoubtedly hold true were it possible of accomplishment, but the segregation of all those suffering with tuberculosis is, from an economic standpoint, impossible.

The principles of disinfection for leprosy should be carried out along the same lines as for tuberculosis, which it so closely resembles, particular attention being paid to the nasal secretions. The Leprosy Investigation Station has found a nasal spray of value in freeing the nasal discharges from the bacilli. The nasal cavity is sprayed three times a day with acetozone inhalant (acetone 1 per cent, chlorotone 0.5 per cent in liquid petrolatum).

Plague—Plague, also called bubonic plague, black death, etc., is a communicable disease caused by the *Bacillus pestis*. Patients suffering with plague may give off the germs of the disease in all the discharges from the body, but especially in the sputum and feces. Plague is communicated largely through the agency of insects, particularly fleas, bedbugs, lice, etc. Rats, mice, squirrels, guinea pigs, monkeys, cats, etc., are susceptible to the disease; and among rats, mice, and squirrels it may occur in fatal epidemic form.

Fleas become infected by feeding on the blood of plague-sick animals, after which they may carry the infection either to other animals or to human beings. Fleas are largely responsible for the transmission of plague, but it may also be transmitted by bedbugs, lice, flies, etc. Although an unsettled question, it is possible that plague infection may be communicated to man through food that has been contaminated by plague-infected rats or insects.

The principal disseminators of plague infections, then, are *rats*, indirectly by having the disease and harboring fleas, which carry the infection from rat to rat; and, second, *fleas* directly by becoming infected from plague-sick rats or humans and carrying the infection to healthy persons.

Isolation—Plague should be isolated in the same manner as has been prescribed above for the isolation of smallpox.

Disinfection—Disinfection in plague prevention is directed largely toward the destruction of rats, mice, fleas, bedbugs, flies, and other animals and insects that may transmit the infection. Rats, mice, squirrels, etc., in a plague-infected territory should be exterminated as completely as possible. Use sulphur dioxide, traps, poison, etc., and as soon as the animals are killed they should be burned. The floor of the sickroom of a plague patient should be sprinkled occasionally with pyrethrum powder in order either to kill the fleas and other insects or to keep them away from the patient. Sweepings from the room should be burned. Sputum, feces, urine, and other discharges from the patient should be disinfected with one of the following solutions: Five per cent phenol, 5 per cent formaldehyde, 2 per cent compound solution of cresol, or lysol, chlorinated lime, etc. Soiled bed linen, towels, handkerchiefs, and other objects that have come in contact with the patient should be disinfected by immersion in one of the disinfectant solutions just mentioned

or by boiling. The hands of the nurse should be washed in a solution of phenol or bichloride of mercury.

Upon the termination of the disease the room should be liberally sprinkled with pyrethrum and then fumigated with sulphur dioxide. Following this fumigation, the mattress should be burned, the bedclothes, etc., burned or boiled, and if any lice or bedbugs are present they should be killed, either with boiling water, gasoline, or in some other way.

Typhus Fever—Typhus fever, also known as spotted fever, jail fever, ship fever, *tabardillo*, etc., is a communicable disease, the cause of which is unknown. The disease is conveyed by the body louse, *Pediculus vestimenti*. The louse, by biting a patient suffering with typhus fever, becomes infected, and it may then transfer the infection to healthy persons by biting them.

Patients suffering with typhus fever should be isolated lest healthy persons entering the sickroom become infested with infected lice.

Disinfection—The preventive measures should be rigidly carried out toward the destruction of the louse. When a case of typhus fever is discovered the patient's clothing should be removed and immediately boiled or placed in a 1 to 500 bichloride of mercury solution in order to kill the lice and their eggs. Another bed should be provided for the patient and the framework of the one just vacated should be scalded with boiling water or the lice killed in some other way. The mattress should be burned, and the bedclothing boiled or placed in a 1 to 500 bichloride solution. Parts of the room likely to harbor lice should be scalded with boiling water. The patient's hair should be clipped and the clippings burned. The patient should then be given a thorough sponging with a 1 to 1000 solution of bichloride of mercury. The discharges from the patient are not thought to contain the infection of typhus fever; therefore their disinfection is thought to be unnecessary.

Following the removal of the patient from the room, the mattress, bedclothing, etc., should be treated as above stated, and then the room should be given a thorough fumigation with sulphur dioxide, as has been prescribed for the destruction of lice. Following the fumigation, the framework of the bed, the floor, walls, etc., of the room should be soaked with boiling water or saturated with petroleum, gasoline, or some other method of killing lice enforced. The use of petroleum, and particularly of gasoline, is of course attended with danger from fire.

Yellow Fever—Yellow fever is a communicable disease, the cause of which has not yet been discovered. The disease is transmitted by the bite of a mosquito, the *Stegomyia calopus*. In order for this mosquito to transmit the disease it is necessary that it be infected by biting a human case of yellow fever. About 14 days after thus becoming infected, it may transmit the disease to non-immune persons by biting them; this it may do during the remainder of its life. It is only in the manner just stated that yellow fever is transmitted from sick to healthy persons.

Yellow fever patients should be isolated on account of the possibility of their quarters harboring infected mosquitoes.

The preventive measures against yellow fever consist of screening the patient and the destruction of the mosquito. The patient, therefore, should be kept in a well-screened room and, as a further precaution, in a bed covered with mosquito netting.

Following the removal of the patient, the room, and preferably the entire building, should be fumigated with sulphur dioxide, as described for the destruction of mosquitoes on page 1836. Pyrethrum may be used, but it is not nearly so efficient for killing mosquitoes as is sulphur dioxide.

Malaria—Malaria is a communicable disease caused by the *Plasmodium* of malaria. It is transmitted only by the bite of a mosquito of the group known as *Anopheles*. The mosquito becomes infected and transmits the disease in a manner very similar to that described for yellow fever.

Administering quinine, screening the patient, and destroying the mosquito are the preventive measures to be carried out against malaria. However, effective screening of the patient becomes a difficult problem when consideration is given to the widespread prevalence of malaria and to the fact that the mosquito may become infected by biting a case of malaria long after the patient has apparently recovered from the disease.

Dengue—Dengue is a communicable disease, the cause of which is unknown, but is transmitted by the bite of a mosquito, the *Culex fatigans*. This mosquito may transmit the disease to non-immune persons by biting them almost immediately after the mosquito has fed on the blood of a patient suffering with dengue.

As to how long the mosquito after becoming infected is capable of infecting non-immune persons is not known.

The measures for preventing dengue should be carried out in the same manner as they are carried out in the case of yellow fever.

PART XIV

BIOLOGICAL PRODUCTS

CHAPTER CXVIII

THE SCIENTIFIC BASIS AND CLASSIFICATION OF BIOLOGICALS

THIS section deals with a group of medicinal and diagnostic agents commonly designated as "Biological Products". The term "biological", serves to distinguish these products from the pharmaceutical preparations and chemical substances, including the vegetable drugs, galenicals, and the organic and inorganic chemicals. The word "biological" also carries the thought of complex products resulting from the *life* activities of animal, plant, or bacterial organisms, as distinguished from those resulting from the simpler chemical and physical processes with which chemists deal. As commonly used, it is a general term or group designation, which includes antitoxins, serums vaccines, tuberculins, pollen extracts and the like.

The production of biological products involves the exercise of the skill of expert laboratory technicians and the practical application of the principles of the science of Bacteriology and related branches of knowledge. Their preparation requires (*a*) the growing and handling of mass cultures of bacteria, (*b*) their treatment by technical processes so that they can be made into vaccines, (*c*) the separation and refinement of the toxins or poisonous products elaborated, (*d*) the production of serums, antitoxins, and antibody solutions, (*e*) the preparation of attenuated viruses, and (*f*) the preparation of protein extracts, etc., by scientific methods. These will be outlined below under the description of each product.

The use of biological products in medicine rests entirely upon the science of *immunology*—the science which treats of the defensive and offensive reactions of the body to infectious or parasitic microörganisms and to foreign proteins. It is therefore necessary to understand something of the processes of immunity before one can appreciate why the so-called biological products have attained such an important place in the prevention and treatment of disease.

IMMUNITY

Immunity is an altered or acquired condition, as a result of which the body adapts itself to the presence of foreign protein, resists the invasive powers of pathogenic microörganisms and protects itself against the deleterious action of their toxic products.

Invading pathogenic organisms irritate or destroy body tissues or blood cells. The injury may be effected either by the toxins which they form or by the poisonous effect of the bacteria themselves. The normal individual will respond to such irritation or invasion by an increased production of white blood corpuscles (leucocytes) and of specific *antibodies*—formless but complex physicochemical substances which appear in the blood and lymph and are capable of neutralizing toxins or antagonizing the bacteria and their products. Since the effects of bacteria are of two kinds, it is not surprising to learn that

there are two distinct types of immunity, namely, *antitoxic immunity* or ability to neutralize toxins, and *antibacterial immunity*, or the ability to destroy the bacteria themselves. The more important distinctions may be readily visualized by the following tabulation[1]:

- Reactions to Infection
  - Increase in white corpuscles
  - Production of antibodies
    - against toxins (antitoxin)
    - against bacteria
      - acting alone
        - dissolving bacteria (lysins)
        - clumping bacteria (agglutinins and precipitins)
      - acting with white corpuscles
        - digesting bacteria (opsonins)

The defensive reactions of the body which give rise to immunity are thus seen to be quite varied. In most diseases probably several of these reactions are going on at one and the same time, but usually one is much more important than the others and is commonly emphasized as the sole protective reaction in a given disease.

There is another conception of immunity which it is important to grasp before one can understand the different kinds of biological products and their uses. We refer to the distinction between two general types of immunity commonly spoken of as "passive" immunity and "active" immunity.

Fig. 783

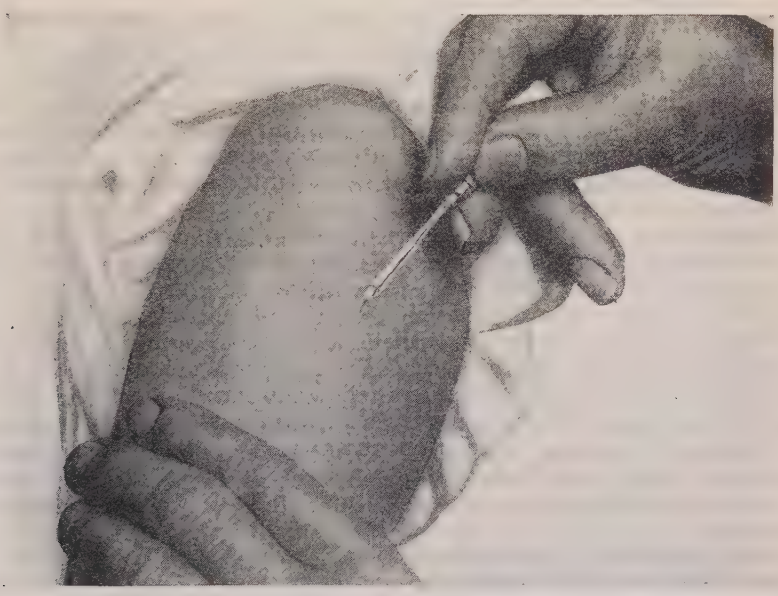
Horse used for the production of Diphtheria Antitoxin

Passive Immunity—Passive immunity is that conferred on a patient by the injection of antitoxins or antibacterial serums. It involves no active response on the part of the patient but gives him the benefit of an excess supply of specific antibodies previously produced in another animal, usually the

[1] Modified from Broadhurst.

horse. The organism concerned is injected into the horse, which reacts by the formation of antibodies. These soon appear in abundance in the blood, and are transferred in the serum to the patient. The latter is merely a passive recipient of protective substances which were produced through the activity of the tissues of the animal whose serum was transferred. Passive immunization is employed in the treatment of acute infections and as a means of supplementing the activity of the patient's own tissues in their efforts to develop sufficient antibodies to destroy the invading organisms and counteract their poisons. Passive immunity is of short duration. The injected antibodies are rather quickly eliminated and their protective influence is gradually lost, so that at the end of two or three weeks, it has practically disappeared.

FIG. 784



The modern method of vaccination against smallpox. Single linear scratch (⅛ inch) through outer layer of skin, upon which droplet of vaccine is expelled from capillary tube and rubbed in gently, with aseptic precautions

Active Immunity—Active immunity is that produced when the cells and tissues of the individual, by their own activities, react to an infection or to an injected antigen, and overcome it by producing and accumulating an excess supply of specific antibodies in the blood and lymph. This type of immunity results only from an active struggle between the body cells and the invading or injected agent. In the words of Kolmer, this battle may be of any degree of severity, ranging from an attack of a disease itself, which may threaten life, down to the most transitory and trivial reaction due to the injection of a minute dose of a mild vaccine. Active immunity may be induced in one or more of three ways. (*a*) By accidental infection, that is, by an actual attack of an infectious disease, such as diphtheria, scarlet fever, measles, etc. (*b*) By artificial inoculation. Before the modern methods of vaccination (see Fig. 784) for smallpox were perfected, this was the common practice in the control of smallpox. Healthy persons were inoculated with the virus from a mild case and thus actually contracted the disease, preferring rather a mild attack while

in health, than to fall a victim to a virulent attack during an epidemic or during ill health. Ex-Senator Beveridge, in his "Life of John Marshall", has made famous the story of how the first Chief Justice of the Supreme Court, as a young man, journeyed on foot from Richmond to Philadelphia to be made proof against the disfiguring malady. (*c*) By vaccination. Vaccination means the injection of an antigenic substance, that is, one which will stimulate the body cells and tissues to the formation of antibodies. The antigens used in vaccination may be living, but modified and attenuated viruses, as in smallpox and rabies vaccination, or killed microparasites and their products, as in bacterial vaccines, or toxins produced by bacteria, as the Scarlet Fever Toxin for immunizing to scarlet fever.

If one inject a guinea pig at weekly intervals with gradually increasing doses of diphtheria toxin, beginning with an exceedingly small dose which will not kill the animal, within five or six weeks a dose can be given that will contain several times the amount of diphtheria toxin which would have killed the animal before the injections began. Repeated injections of small doses of the toxin result in the development of a resistance on the part of the animal, so that it can soon withstand many times the minimum fatal dose. Such an experiment illustrates the development of active immunity of a kind which is spoken of as antitoxic. *Antitoxic immunity* is that induced by either accidental or purposeful injections of toxins.

Monkeys have been vaccinated with pneumococcus vaccines and, after a suitable interval, were experimentally infected with a virulent strain of the pneumococcus. It was found that they were completely protected. The monkeys did not contract pneumonia even when the living virulent pneumococci were introduced directly into the lungs. This experiment illustrates an antibacterial immunity, as distinguished from antitoxic immunity. Practically everyone knows of the immunity which follows an attack of typhoid fever and that which can be produced by anti-typhoid vaccination. These are examples of *antibacterial immunity*—a form of resistance to the infecting organisms themselves, which is generally dependent upon the production and presence of various antibodies (lysins, opsonins, agglutinins, etc.) in the circulating body fluids.

Active immunity of the antitoxic type is of considerable duration, often persisting for years, as in diphtheria and scarlet fever. The duration of antibacterial active immunity is variable. In some cases it is quite short, as that following a common cold, while anti-typhoid vaccination may protect for a period of perhaps two years, and smallpox vaccination for a period of seven years or longer.

Antigens—Antigens have been defined as substances which stimulate the production of protective substances or antibodies. It happens that not only will living bacteria and viruses act as antigens, but also their soluble products (toxins) and other protein substances. In general, any complex protein substance, whether "organized", as in the case of bacteria or red blood cells, or "unorganized", as the white of egg, serum proteins, etc., may, in some degree act as an antigen. In an infectious disease, therefore, the invading organism acts as an antigen because it stimulates the body to the production of protective substances. Likewise, dead microörganisms in the form of bacterial vaccines, or their soluble products in the form of toxins act as antigens. Soluble proteins, when injected parenterally, that is, by any route other than the intestinal tract, also act as antigens and cause the production of specific antibodies.

Protein Sensitization—This brings us to the difficult and complex subject of protein sensitization, which requires consideration in any discussion of

immunity. A few fundamental facts will help explain the use in medicine of such biological products as the pollen, and other protein, extracts. Protein substances such as white of egg, and muscle-substance protein (meat), when taken into the alimentary canal, are broken down by digestion into simpler, harmless substances before they are absorbed through the wall of the intestine into the blood. If these proteins, instead of being taken by mouth, were injected directly into the blood stream, an unusual condition would be set up because the blood does not contain enzymes or ferments necessary to effect their digestion; hence the term "foreign proteins". Foreign proteins act as antigens and the cells of the body are stimulated to dispose of them in some way or to become adapted to their presence.

Protein sensitization manifests itself in many different ways—most dramatically in the phenomenon known as *anaphylaxis*. This abnormal sensitiveness may be demonstrated experimentally as follows. An initial dose of some foreign protein, horse serum, for example, is injected into a guinea pig or rabbit. If, after an incubation period of ten to twelve days, a second fairly large dose is injected, symptoms of a more or less violent character appear. The reaction is manifested chiefly by the contractions of the involuntary or smooth muscles. In the guinea pig this affects particularly the smooth muscle fibers of the bronchi, producing marked respiratory distress and perhaps resulting fatally. In the rabbit, the reaction apparently selects the smooth muscle fibers in the walls of the arterial system of the lungs, with the effect that circulation through the lungs is stopped and the animal dies through oxygen starvation of the remainder of the body. Other animals react in other ways. The animal is said to be "sensitized" by the first injection, with the result that a second dose of the same protein in a sub-lethal quantity for a normal control, and given after a suitable interval, will cause the death of the animal.

Although easily produced in animals, anaphylaxis is fortunately rather rarely observed in the human subject.

There are, however, many other manifestations of protein sensitization of a less severe type. Hay fever, urticaria, serum sickness, asthma, eczema, etc., are examples. A long list of proteins—food, animal, epidermal, bacterial, and pollen—have been incriminated as the inciting agents. One authority estimates that about one per cent of the population of the United States suffers from hay fever. It is the most prevalent form of sensitization. The main factors in this disorder are the wind-borne pollens. When present in inspired air they impinge upon the mucous membranes of the nasal passages and some of their soluble substances are absorbed. This sets up a train of symptoms in pollen-sensitive individuals, marked by congestion and irritation of the respiratory mucous membranes and by catarrh, paroxysmal sneezing, itching, etc. Some are sensitive to one or more of the tree pollens, such as the willow, oak, walnut, maple, and others which pollinate in the early spring. Other patients are sensitive to one or more of the grass pollens, especially timothy, and suffer from hay fever during the pollinating period of this plant in the latter part of May and June. A still larger group is sensitive to some one or more of the numerous wind-borne pollens of late summer and autumn, particularly the ragweeds in Eastern United States and the wormwoods and sagebrush in the western half. There are certain localities, as for example, in the Southwest, where climatic conditions permit plant growth throughout the year, with a succession of pollinating periods, so that sensitive individuals are in discomfort practically the year round. This is the so-called perennial hay fever. Many of the common weeds which pollinate in the late summer and early fall are

factors in hay fever of a mixed type. While some hay fever sufferers are sensitive to but one pollen, the majority are sensitive to two or more, but these are usually closely related botanically.

Asthma, in some of its forms, constitutes another example of protein sensitization. A large number of inciting factors have been identified in this disease. Some patients, for example, are found to be sensitive to house dust or mill dust. Others are sensitive to horse dander and cannot enter a stable without developing an attack. Some asthmatics suffer acute attacks if they have to sleep on a feather pillow. Others are sensitive to sheep wool, and in some, the asthmatic symptoms are caused by pollens.

Serum sickness is a manifestation of protein sensitization with which the physician is frequently concerned. The ordinary form of serum sickness appears usually from eight to thirteen days after the injection of the serum, and is characterized by a rash and skin eruption together with some edema or swelling and joint pains and sometimes a slight fever. Sometimes it manifests itself by an immediate stormy reaction resembling shock. Such immediate reactions occur usually after the first dose of the serum and develop only in those individuals who are naturally sensitive to horse serum. Natural sensitiveness to horse serum is fortunately rare—about one patient in twenty thousand according to one authority. Most individuals are normal with respect to sensitivity to horse serum and can be given a dose of antitoxin or serum without any immediate or severe reactions. These patients are more likely to show more pronounced symptoms of serum sickness following a second dose of serum than after the first.

The mild, delayed form of serum sickness is not serious and excites no alarm. The immediate or shock reaction, however, must be avoided as far as possible. Physicians should take the precaution to determine, before giving the first injection of a serum, whether the patient is sensitive to horse serum. This is particularly important if the patient gives a history of asthma, for it may be that the asthma is a symptom of sensitiveness to horse protein. In any case, sensitiveness can be readily determined by making a preliminary skin test. This is done by injecting a very small amount, $\frac{1}{20}$ to $\frac{1}{10}$ of a cc., between the layers of the skin. If the patient is sensitive, a noticeable reaction will appear within twenty minutes to one-half hour, in the nature of an area of redness with development of a wheal around the site of injection. One who is not sensitive to horse serum develops no reaction and may safely be given ordinary therapeutic doses of serum.

Serum treatment of those who show a positive reaction must be carried out very carefully, usually beginning with a very small dose, a fraction of a cc., and gradually increasing this at hourly intervals, until 1 cc. can be given without causing a reaction. Doses may then be more rapidly increased, until the required therapeutic dose has been administered.

Treatment of the many forms of protein sensitization may be carried out along different lines. The simplest method, of course, is to avoid or remove the specific cause of illness. If this cannot be done, specific protein treatment is the method of choice. Specific protein treatment means the partial or complete relief of the symptoms by subcutaneous injections of a suitable preparation of the specific protein, found by test to be the causative factor. It is necessary to begin the injections with very small sub-toxic doses. These can be increased very gradually. Usually they must be continued over a considerable period of time. The doses may be given at short intervals, with the object of increasing the patient's tolerance as rapidly as possible. The duration of the immunity or tolerance gained by this method of treatment varies greatly. In hay fever, for

example, one authority states that one cannot rely upon the duration of tolerance lasting more than six to eight weeks. For this reason hay fever sufferers usually have to repeat the treatment preceding the onset of symptoms each season.

In the treatment of other forms of protein sensitization there are marked irregularities in the results, which may be accounted for by difficulties in making accurate specific diagnosis, by differences in the degree of the sensitiveness of the patient and by differences in the intensity of exposure. Developments in this branch of Immunology are appearing rapidly and the pharmacist who makes some effort to keep in touch with them will be in the best position to render service on biological products.

CLASSIFICATION OF BIOLOGICAL PRODUCTS

The subject of immunity to infectious diseases and of tolerance to foreign proteins has been discussed briefly, in order to provide a sufficient background for understanding the different kinds of biological products which the pharmacist is called upon to handle and the different uses to which they are put in the treatment and prevention of disease. The biological products generally used in medicine today fall into distinct groups, which may be outlined as follows:

CLASSIFICATION OF BIOLOGICAL PRODUCTS

Antitoxins *Serums* *Antibody Solutions*	*For Passive Immunization*—in treatment of acute diseases and for temporary prophylaxis.
Toxins and *Toxoids* *Toxin-Antitoxin Mixture* *Tuberculins* *Bacterial Vaccines (Bacterins)* *Sensitized Bacterial Vaccines (Serobacterins)* *Viruses*	*For Active Immunization*—in treatment of chronic diseases and for prophylaxis. Bacterial vaccines, both plain and sensitized, sometimes used in acute diseases.
Proteins—Foreign Protein Therapy—specific and non-specific.	
Diagnostic Reagents	Include many products under the above groups, especially the *toxins*, *tuberculins*, and *proteins*, used in the specific diagnosis of disease.

The groups are more clearly defined and the individual preparations are described in the following pages.

Dating, Preservation and Dispensing—There are some practical points which apply to all biological products and are of great importance to the pharmacist, both in his professional capacity and as a means of preventing unnecessary losses.

The potency of biological products in general tends to decrease or fall off more or less rapidly with the lapse of time. Their period of potency is greatly prolonged by preserving them at low temperatures. This is nowhere more clearly shown than in the data which was first worked out by Dr. W. F. Elgin for smallpox vaccine. It was found that the potency of vaccine virus was lost within three or four days by exposure to temperatures of 98° F. (37° C.); it was greatly weakened or lost by one to three weeks' exposure at 70° F. (21° C.); at ordinary refrigerator temperatures of 50° F. (10° C.), the virus was still active after three or six months; at 10° F. (−12° C.) it remained active for four years.

Cold storage is just as important for the pharmacist as for the manufacturer, and physicians will usually give preference, in purchasing biologicals, to the pharmacist who is equipped to keep the products continually at a low temperature while in his possession.

NOTE—In spite of the importance of refrigeration in preserving biological products, *freezing should be avoided*. This precaution is particularly important in the case of Diphtheria Toxin-Antitoxin Mixture. Some unfortunate experiences have shown beyond a doubt that freezing was responsible for some change in the Toxin-Antitoxin Mixture by which the toxin was left under-neutralized. Its use subcutaneously was followed by severe constitutional reactions and painful local inflammations. Freezing probably has some injurious effect on some other biological products.

Not only the temperature of the storage space but the time that the package remains on the shelf is a very important consideration. Some loss of potency occurs even at the lower temperatures. Because of the effects of temperature and age, United States Federal laws require that packages of most biological products be marked with an "expiration date", beyond which the contents cannot be expected, beyond a reasonable doubt, to yield specific results. The regulations may be briefly summarized as follows:

Dating of Biological Products—Official antitoxins and those subject to official potency tests, with

20 per cent excess potency, 1 year
30 per cent excess potency, 2 years
40 per cent excess potency, 3 years
50 per cent excess potency, 4 years

Anti-Anthrax, Antidysenteric, Antipneumococcic, Antistreptococcic Serum, 1 year from date of manufacture or issue.

Other immune serums, 6 months.

Normal serums, 3 years.

Vaccine Virus, 3 months, "if kept below 5° C. (41° F.)", and 2 months, when issued between May 1st and September 15th.

Rabies Vaccine, killed virus, 6 months.

Rabies Vaccine, living virus, in less than 50 per cent glycerin, 21 days after emulsification; in an emulsion containing at least 50 per cent glycerin, 1 month.

Tuberculins, concentrates, 5 years; dilutions, 1 year.

Bacterial Vaccines, 18 months.

Sensitized Vaccines (Serobacterins), 18 months.

Modified bacterial derivatives, 18 months.

Diphtheria Toxin-Antitoxin Mixture, 6 months.

Diphtheria Toxin for Schick Test, 6 months, "if kept between zero and 8° C. (32 to 46.4° F.)". In the absence of such proviso, 1 month.

Pollen extracts, animal, vegetable and bacterial protein extracts, 1 year.

The fixing of an expiration date does not necessarily mean that the products lose all their potency when the period has expired, but simply that past experience has shown that there is more or less loss within that period, so that after the expiration date, the full therapeutic effects cannot be expected. Most biological products are subject to a return privilege for credit or exchange. While this is necessary, in view of the nature of the products, abuse of the privilege is to be avoided by carefully anticipating current local needs and stocking only enough biological products to meet demands likely to arise over a limited period of time.

In dispensing biological products the pharmacist is dealing with preparations, most of which are intended for use by injection, either subcutaneously, intramuscularly or directly into the vein. It is therefore of paramount importance that the sterile condition of the preparations be maintained up to the time they are actually injected. Sterility is assured by the processes used in the manufacturing establishments, and no product is released until repeated tests have shown the product to be safe in this respect. The pharmacist contributes his part to the maintenance of sterility of the product and safety to the patient by observing the requirements of the U. S. P. X, for the official antitoxins, *viz.*, that *they must be dispensed in the unopened glass containers in which they were placed by the manufacturing establishments.*

CHAPTER CXIX

BIOLOGICAL PRODUCTS USED FOR PASSIVE IMMUNIZATION

ANTITOXINS

Antitoxins are antitoxic serums, usually more or less concentrated and purified by the removal of some of the non-essential serum constituents. They confer passive antitoxic immunity and are used in the specific treatment of the acute manifestations of disease.

Official Products—Two antitoxins are recognized by the U. S. P. X, namely, Diphtheria Antitoxin and Tetanus Antitoxin. The former is now official only in the refined or concentrated form, while Tetanus Antitoxin is official in two forms—the concentrated and the crude.

Legal Control—The official antitoxins must be prepared in an establishment licensed by the Secretary of the Treasury of the United States. The requirements for labeling are that the outside label must bear the name of the antitoxin and the minimum number of units in the package, the lot number of the antitoxin, the name, address and license number of the manufacturer, and a statement of the date beyond which the minimum potency may not be maintained. This date is one year from date of issue from the manufacturing establishment if an excess of 20 per cent over the minimum potency has been placed in the container, two years for a 30 per cent excess, three years for a 40 per cent excess, or four years for a 50 per cent excess.

The strength shall be expressed in units of antitoxic power, and the unit shall be that of the standard antitoxin distributed by the Hygienic Laboratory of the United States Public Health Service.

ANTITOXINUM DIPHTHERICUM. U.S. Diphtheria Antitoxin

[**Antitox. Diph.**—Serum Antidiphthericum Purifactum U. S. P. IX, Purified Antidiphtheric Serum, Concentrated Diphtheria Antitoxin, Refined Diphtheria Antitoxin, Antidiphtheric Globulins]

Diphtheria Antitoxin is an aqueous solution of certain antitoxic substances obtained from the blood serum or plasma of an animal of the genus *Equus*, which has been properly immunized against diphtheria toxin. After the serum or plasma from the immunized animal has been collected, the antitoxin-bearing globulins are separated from the other constituents of the serum or plasma and dissolved in water. Sodium chloride and a preservative are then added and the solution is filtered through a bacteria-excluding filter. It has a potency of not less than 350 antitoxin units per cc.

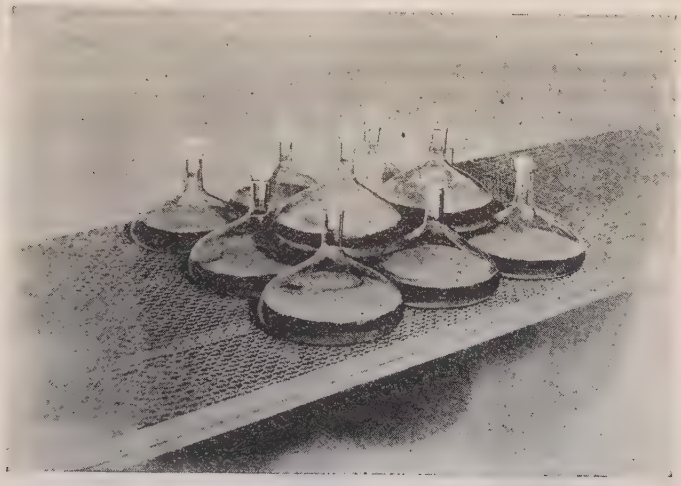
Description and Physical Properties—A transparent or slightly opalescent liquid, with sometimes a slight granular deposit, of a faint brownish, yellowish or greenish color, nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. Diphtheria Antitoxin must come from healthy animals, must be sterile, free from toxins, and must not contain an excessive amount of preservative (not more than 0.5 per cent of phenol or 0.4 per cent of cresol, when either of these is used) and the total solids must not exceed 20 per cent.

Uses—Diphtheria Antitoxin is the specific curative agent in the treatment of diphtheria. Its administration accomplishes two things, provided it is given in adequate dosage and sufficiently early in the course of the disease. (1) It neutralizes diphtheria toxin in the blood and body fluids and possibly the toxin which is in contact with, or united to, the tissue cells. (2) Adequate dosage supplies the patient with an excess of antitoxin, which serves to neutralize any

further toxin production as long as virulent diphtheria bacilli remain. The antitoxin also influences the destruction and removal of the bacilli which produce the toxin.

Benefit from the use of Diphtheria Antitoxin depends largely on the method and time of administration and the size of the dose. All authorities emphasize the importance of introducing the Diphtheria Antitoxin into the circulation as soon as possible after infection has occurred. In view of the importance

FIG. 785



Flasks on shelf in incubator showing growth of Diphtheria Bacilli in the production of Diphtheria Toxin

of the time factor it is generally recommended that antitoxin be given to every patient upon the mere suspicion of diphtheria, making bacteriological diagnosis afterward.

With reference to the methods of administration, the subcutaneous route is used only in the treatment of mild cases. Any part of the body where there is an abundance of subcutaneous cellular tissue may be selected. The intrascapular region is usually preferred. In moderate cases intramuscular injections are recommended. The gluteal region or the anterior part of the thigh offer suitable sites. Absorption is three to four times more rapid than from subcutaneous injections. Intramuscular injections, if properly carried out, are no more painful than subcutaneous injections, and because of the more rapid absorption are recommended for routine use. In severe and malignant cases and in all cases seen late in the disease it is important to introduce the antitoxin into the circulation at the earliest possible moment. Intravenous injection is therefore the method of choice.

Diphtheria Antitoxin is also used for prophylactic or protective purposes. To those who have been exposed to diphtheria by contact with cases and have not themselves developed the symptoms, immediate though temporary protection is conferred by the injection of 1000 units Diphtheria Antitoxin. This gives a temporary, passive immunity which protects the individual against infection for a short time. This protection lasts little more than two weeks, and is therefore limited to prophylaxis in persons actually exposed to the disease and finds its chief value in the presence of epidemics. A more or less permanent

active immunity to diphtheria is conferred by the use of Diphtheria Toxin-Antitoxin Mixture, see page 1916.

Dose—The Pharmacopœia states the average dose as, curative, 10,000 units, protective, 1000 units. In practice, physicians gauge the curative dosage by the severity of the symptoms and the stage of development of the disease. In very mild cases, treated early, 3000 to 5000 units is often sufficient. An average dose of 10,000 units should be regarded as a minimum initial dose in severe cases and in those seen late. The dosage may be repeated at short intervals, if indicated. There is apparently no danger of an overdose. It is the practice to reduce the dosage by one-half for infants under twenty pounds, and a one-third reduction is recommended for children under fifty pounds. Otherwise, the dosage given applies to all age groups. The protective or preventive dose of 1000 units is standard practice.

Dosage Forms Available—Commonly supplied in 1000 unit, 3000 unit, 5000 unit, 10,000 unit and 20,000 unit containers.

Manufacturers—1, 2, 6, 8, 14, 17, 45, 52, 56, 63, 64, and 65.[1]

FIG. 786

Relative difference in volume between unconcentrated antitoxic serum (A), antitoxin of the usual concentration (B), and super-concentrated antitoxin (C) of the same strength (10,000 units)

Unofficial Diphtheria Antitoxin

DIPHTHERIA ANTITOXIN SUPER-CONCENTRATED

In the words of the N. N. R., this product resembles Diphtheria Antitoxin, U. S. P., but differs in that the volume per thousand units is smaller and the protein content is claimed to be lower.

Preparation—The method of preparation is the same as that for Diphtheria Antitoxin, U. S. P., except that certain refinements and improvements in the method of concentration are applied by which antitoxin-bearing globulins of higher potency are obtained.

Uses—Has the same indications as Diphtheria Antitoxin, U. S. P., with the claim that its use causes less pain to the patient and is more quickly absorbed because of its smaller volume. The dosage, in terms of unit strength, is the same as that of the official preparation.

Dosage Forms Available—Supplied in 1000 unit, 3000 unit, 5000 unit, 10,000 unit and 20,000 unit syringe packages.

Manufacturer—2.

[1] The numbers refer to the licenses issued by the United States Public Health Service to manufacturers of Biological Products. A key will be found at the end of Chapter CXXII, page 1936.

ANTITOXINUM TETANICUM. U.S. Tetanus Antitoxin

[**Antitox. Tet.**—Serum Antitetanicum Purificatum U. S. P. IX, Purified Antitetanic Serum, Concentrated Tetanus Antitoxin, Refined Tetanus Antitoxin, Antitetanic Globulins]

Tetanus Antitoxin is an aqueous solution of certain antitoxin-bearing substances obtained from the blood serum or plasma of an animal of the genus *Equus*, which has been properly immunized against tetanus toxin. After the serum or plasma from the immunized animal has been collected, the antitoxin-bearing globulins are separated from the other constituents of the serum or plasma and dissolved in water. Sodium chloride and a preservative are then added and the solution is filtered through a bacteria-excluding filter. It has a potency of not less than 300 units per cc.

Description and Physical Properties—A transparent or slightly opalescent liquid, with sometimes a slight granular deposit, of a faint brownish, yellowish or greenish color, nearly odorless, or having an odor due to the presence of the antiseptic used as a preservative. Tetanus Antitoxin must come from healthy animals, must be sterile, free from toxins, and must not contain an excessive amount of preservative (not more than 0.5 per cent of phenol or 0.4 per cent of cresol, when either of these is used) and the total solids must not exceed 20 per cent.

Uses—Tetanus Antitoxin must be considered rather as a preventative than as a curative agent, as best results are obtained when the antitoxin is routinely administered before the tetanus toxins have invaded the motor nerve cells. Conditions favoring the growth of tetanus bacilli are found in contused, lacerated wounds, in which destruction of tissue and blood has occurred.

"It should be the universal rule to give a prophylactic dose of 1500 units of antitoxin to all patients who have received lacerated or penetrating wounds. If the wounds contain necrotic tissue or a suspected foreign body, the dose should be repeated in ten days and subsequently if operation on the wound is contemplated[2]." Deeply seated wounds which heal on the surface are especially dangerous, as also puncture wounds from nails and Fourth of July accidents. Statistics of its use in armies have fully demonstrated the protective value of tetanus antitoxin in wounds occurring in warfare. Wounds occurring in or about stables or on the farm, where manure, one of the best carriers of tetanus bacilli, is present, should be treated as soon as possible, and the injection of an immunity dose of Tetanus Antitoxin should be regarded as standard routine practice.

Treatment of tetanus is not as satisfactory as the protective use of the serum. Tetanus toxin has a special affinity for nerve tissues, and eventually fixes itself to the nerve cells of the spinal cord. Since this fixation of the toxin in the nerve cell cannot be reversed, the object of treatment is to administer large quantities of *antitoxin* at the earliest possible moment in an attempt to neutralize the toxin before fixation has had time to proceed to a dangerous extent. Therefore, if the symptoms of the disease have appeared, an attempt should be made at once to saturate the patient with antitoxin by the quickest possible method. For this reason authorities recommend either intravenous or intraspinal injections or both.

Dose—The curative dose stated by the Pharmacopœia is 10,000 units. This is usually greatly exceeded. Therapeutic doses of from 30,000 to 40,000 units, repeated daily, are often given, and occasionally even larger doses have been used.

The protective or immunity dose is 1500 units. This dose should be repeated

[2] Stone, W. J., *J. A. M. A.*, *78*, 1943, June 24, 1922.

every eight to ten days, as long as the condition of the wound indicates the possibility of the continued presence therein of tetanus bacilli or its spores.

Dosage Forms Available—Commonly supplied in 1500 unit, 5000 unit and 10,000 unit containers.

Manufacturers—1, 2, 6, 8, 14, 17, 45, 52, 56, 63, and 65.

ANTITOXINUM TETANICUM CRUDUM. U. S. Crude Tetanus Antitoxin

[**Antitox. Tet. Crud.**—Serum Antitetanicum U. S. P. IX, Antitetanic Serum, Crude Antitetanic Serum, Unconcentrated Tetanus Antitoxin, Unrefined Tetanus Antitoxin]

Crude Tetanus Antitoxin is a fluid, having a potency of not less than 150 units per cc., separated from the coagulated blood of an animal of the genus *Equus*, which has been properly immunized against tetanus toxin.

Description and Physical Properties—A yellowish or yellowish-brown, transparent, or slightly turbid liquid with sometimes a slight granular deposit, having the faint odor of horse serum or having an odor due to the presence of the antiseptic used as a preservative. Crude Tetanus Antitoxin must come from healthy animals, must be sterile, free from toxins, and must not contain an excessive amount of preservative (not more than 0.5 per cent of phenol or 0.4 per cent of cresol, when either of these is used) and the total solids must not exceed 20 per cent.

Uses—Crude Tetanus Antitoxin can be used in the same way as the refined or concentrated product, but in considerably larger volume of liquid for the same number of antitoxic units. In this country the crude product finds practically no use in human medicine. The manufacturers referred to under the refined antitoxin are, of course, equipped to supply it, but none list it. Most of the lower unit Tetanus Antitoxin finds its way into veterinary practice.

Unofficial Antitoxins

SCARLET FEVER STREPTOCOCCUS ANTITOXIN (CONCENTRATED)

(Scarlet Fever Antitoxin. Scarlatinal Antitoxin)

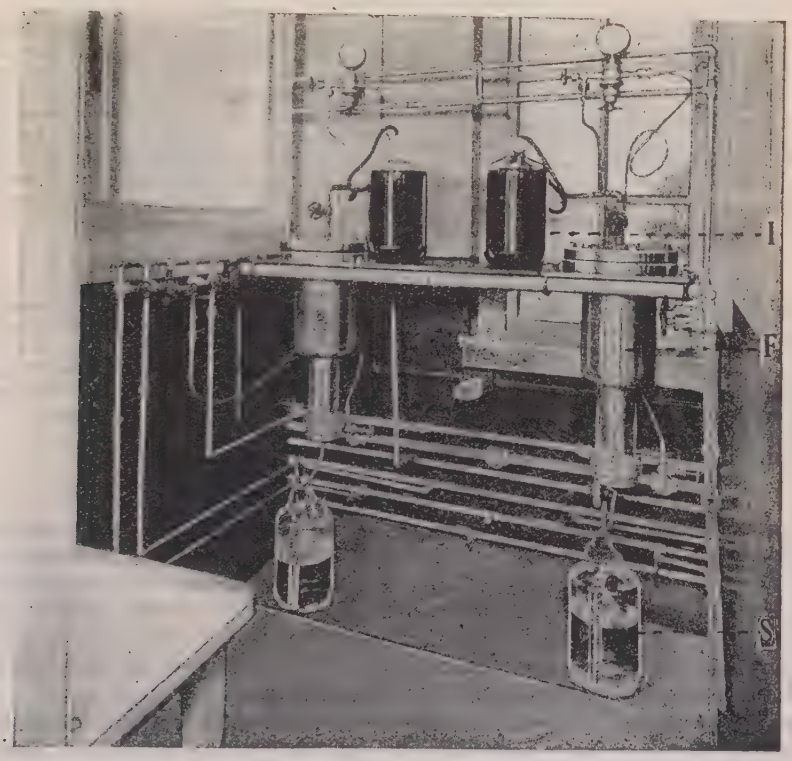
The approved product is the result of research work carried out by Drs. G. H. and G. F. Dick at the McCormick Memorial Institute for Infectious Diseases in Chicago. The method of preparation and the standards are protected by a patent now administered by a Scarlet Fever Committee. It is manufactured under license granted by the Scarlet Fever Committee.

Preparation—Normal, full-grown horses are used, after a ten-day period of observation in quarantine has shown them to be free from disease. The horses are injected subcutaneously with toxin from broth cultures of the scarlet fever streptococcus. The injections are increased gradually up to the limit of tolerance. When potency reaches a satisfactory stage the horses are bled regularly until large amounts of serum have been collected. The serum or plasma is then purified and concentrated by the method used for the concentration of Diphtheria and Tetanus Antitoxin. A preservative (phenol to make 0.35 per cent) is added and sterility effected by passing the antitoxin through germ-removing filters (see Fig. 787). Sterility and potency tests are carried out by the manufacturers, who must then submit samples of each lot to both the U. S. Public Health Service and to the Scarlet Fever Committee, Inc. The antitoxin is released for distribution only upon passing check tests in the laboratories of these two organizations.

Description and Physical Properties—A transparent or slightly opalescent liquid, having much the same appearance as Diphtheria Antitoxin or Tetanus Antitoxin. Possesses a faint amber-yellow or greenish color. Potency is expressed in terms of the number of "skin test doses" which it will neutralize. A "skin test dose" is the amount of scarlet fever toxin which will produce a mild reaction consisting of an area of redness at the point where the toxin has been injected between the layers of, not under, the skin. One thousand times this amount of toxin, that is, 1000 "skin test doses", if injected into one who is not immune to scarlet fever, will produce transient symptoms of the disease. The present potency requirement for the antitoxin is that sufficient to neutralize fifteen times this quantity of toxin. In other words, it must contain enough antitoxin per cc. to neutralize at least 15,000 skin test doses.

Uses—Used in the treatment of scarlet fever. When administered early and in adequate dosage, it has a remarkable curative action, usually bringing about a reduction of the temperature and relief of most of the symptoms within twenty-four hours. Its early use also apparently reduces the incidence of the serious complications and sequellæ which otherwise often follow. Used late in the disease its value is less marked and it has little or no effect in the control of complications and sequellæ once they have developed. It is also used as a prophylactic or preventative. A prophylactic immunity dose is administered to contacts and susceptible individuals who have been directly exposed to scarlet fever infection. Like the prophylactic use of Diphtheria Antitoxin, it gives an immediate passive immunity which will protect the recipient from scarlet fever for a period of two weeks or a little more, and is

FIG. 787



Filtering crude serum to remove broken cells, shreds of fibrin, etc. (I) Immune serum, (F) filter, containing porcelain or clay "candle" through which the serum is forced under pressure, (S) sterile serum ready for finishing process and filling into containers

therefore useful only for the protection of contacts in the home where a case has already developed and for the quick control of an epidemic. An active immunity, presumably more or less permanent, can be developed through the use of Scarlet Fever Streptococcus Toxin—Immunizing, see page 1916.

Dose—Approved Scarlet Fever Antitoxin, manufactured under license from the Scarlet Fever Committee, Inc., is supplied in two dosage forms only, one known as the "therapeutic dose", supplied in syringes containing not more than 14 cc. of antitoxin; the other, known as the "prophylactic dose" syringe, contains one-half the contents of the therapeutic dose. In treatment, one therapeutic dose is usually sufficient in cases treated early and in mild attacks. Sometimes two, rarely three or four "therapeutic doses" are required.

Dosage Forms Available—Commonly supplied in syringe packages of two sizes—therapeutic dose and prophylactic dose.

Manufacturers—2, 52.

SCARLET FEVER STREPTOCOCCUS ANTITOXIN (Dochez Method)

The United States Public Health Service has also issued a license to manufacture Scarlet Fever Antitoxin by the Dochez method, and the product is described in the N. N. R. By the method of Dr. A. R. Dochez, horses are immunized against the specific scarlet fever organism by the localization of living streptococci in a subcutaneous agar nodule, in which they grow and stimulate the production of antitoxic and antibacterial substances. The standard established by the U. S. Hygienic Laboratory is that 1 cc. of the final product must neutralize and hold in neutralization for forty-eight hours not less than 1000 skin test doses of control toxin supplied by the U. S. Hygienic Laboratory. The product actually supplied is in concentrated form and is claimed to neutralize 20,000 skin test doses.

Manufacturer—56.

BOTULINUS ANTITOXIN

Outbreaks of botulism—a type of food poisoning—often occur and sometimes assume epidemic proportions. The symptoms are caused by the toxins of the Bacillus Botulinus; and usually appear only after a definite incubation period of from eighteen to thirty-six hours. It has been found that there are two distinct toxins, and that they have an affinity for the central nerve system. A very small amount of toxin-containing food is enough to cause symptoms and death. When cases appear the need for antitoxin is urgent. As in the case of tetanus, Botulinus Antitoxin must be given early if it is to be effective. The antitoxin is available commercially through only one source. At the present time only one license has been issued by the United States Public Health Service—to the Agricultural Experiment Station, College of Agriculture, University of Illinois, License No. 81.

PERFRINGENS ANTITOXIN (ANTI-GAS-GANGRENE SERUM)

The Bacillus Perfringens is one of the causative factors of gas gangrene. A hemolytic poison or toxin is produced by its growth in muscles. Antitoxic serums have been produced and best results seem to have followed their prophylactic use. Intramuscular injection in the vicinity of the wound together with intravenous administration is advised. The Hygienic Laboratory has established standards for Perfringens Antitoxin and license has been issued for its manufacture.

Dosage Form Available—Supplied in 100 cc. bottles.

Manufacturer—2.

ANTIBACTERIAL SERUMS

Antibacterial serums are antagonistic to bacteria. They attack the germs themselves and for this reason are to be clearly distinguished from the antitoxic serums or antitoxins. As noted in the preceding section, antitoxic serums neutralize the toxin or poison produced by certain germs. Antibacterial serums, on the other hand, contain antibodies which act in a very different way. They contain one or more of several kinds of antibodies, of which the better known are briefly defined as follows:

Bacteriolysins—Bactericidal Antibodies which kill by actually dissolving or disintegrating the bacterial cells. They act only in the presence of complement—a substance which is present in fresh blood.

Bacteriotropins—These antibodies do not destroy bacteria by direct action, but promote phagocytosis, that is, they in some way affect the invading bacteria so that they are rendered defenseless and taken up easily by the phagocytes or white blood corpuscles. Bacteriotropins are not injured by moderate heat.

Opsonins—Antibodies similar in function to the bacteriotropins but different in that they are easily destroyed by moderate heat.

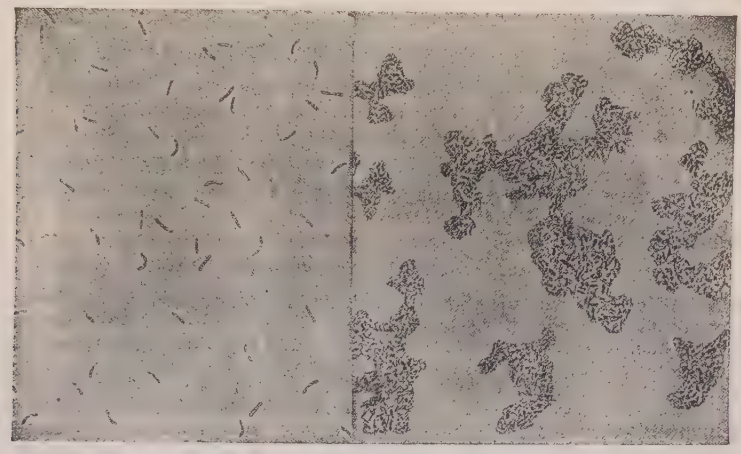
Agglutinins—Agglutinins are antibodies which act directly on the bacteria without complement, causing them to come together in clumps.

Precipitins—Precipitins act on solutions of bacterial substances, causing them to precipitate. Many regard precipitins and agglutinins as identical.

It will be seen, from the number of different kinds of antibodies, that the action of antibacterial serums is much more complicated than that of the

antitoxins. The production of potent antibacterial serums is correspondingly difficult. Their therapeutic value is not so clearly defined nor as well established as that of the antitoxins. There are several reasons for this. One is found in the fact that antibacterial antibodies are associated with a different serum globulin, and, up to this time, it has not been found practical to concentrate them successfully. The antibacterial substances cannot, therefore, be prepared in the degree of purity and concentration which characterizes the antitoxins. The antibacterial serums are unconcentrated and, comparatively

FIG. 788



Showing action of an agglutinating serum. Left: Appearance under microscope of a suspension of free swimming typhoid bacteria. Right: Same after addition of serum containing typhoid agglutinins. Typhoid organisms are massed together in clumps. From Thomas and Ivy, Applied Immunology. J. B. Lippincott Co.

speaking, low in antibody content. Specificity of the antibodies must be taken into account in preparing and using antibacterial serums. This is nowhere more clearly seen than in the case of meningococcus and antimeningococcic serum. Four distinct types of the meningococcus have been found and it has been shown that serum containing antibodies effective against one of these types is not effective against the other three. So with antipneumococcic serum. Type I antipneumococcic serum is not effective against Type II or Type III organisms. In other words antibacterial serums are effective, as a rule, only against the particular strains or types of the organism used in producing the serum.

Unofficial Antibacterial Serums

ANTI-ANTHRAX SERUM

Serum Antianthracicum—A serum prepared by immunizing horses or other animals with anthrax bacilli and their spores.

Uses—Anti-Anthrax Serum is specific in the treatment of anthrax. Results reported are generally favorable to the curative value of the serum in both human beings and in animals. Localized anthrax of the skin (malignant pustule) occurs more or less frequently in human beings, especially among workers in hair, wool and hides. Infected shaving brushes, hairbrushes, or other articles made of hair are sometimes concerned in carrying the infection.

The pustule of cutaneous anthrax frequently heals spontaneously if not subjected to any interference. On the other hand, anthrax septicemia is practically always fatal. The object, therefore, in treating cutaneous anthrax, is first to prevent development of septicemia. It is recommended that, immediately upon diagnosis, the patient should be given an injection of anti-anthrax serum. If the lesion is small an intramuscular injection of 40 to 50 cc. of the

serum is given, while if the lesion is large, together with marked symptoms, it is better to give 50 to 100 cc. intravenously. Excision is the only surgical remedy countenanced. Incision or other manipulations of the lesion are to be avoided as they may start infection of the blood stream. An additional safeguard against septicemia may be derived from the local injections of anti-anthrax serum around the base of the pustule for the purpose of walling off the lesion. Injections of from 2 to 3 cc. each are given at several points so as to circumscribe the lesion. These are repeated two or three times in twenty-four hours, depending on the severity of the case. The local injection method is advised, particularly when excision is refused or cannot be done.

Treatment of internal anthrax or anthrax septicemia must be carried out very vigorously because the cases are so much more severe and highly fatal.

Dose—In malignant pustule or cutaneous anthrax, 40 to 50 cc., intramuscularly, in mild cases; 50 to 100 cc., intravenously, in the more severe, supplemented by excision of the lesion or by walling off the lesion by means of local serum injections, or both. The serum treatment of anthrax bacteriemia calls for intravenous administration of the serum in 100 to 200 cc. doses, frequently repeated until the condition of the patient indicates improvement. The serum has been given in 200 cc. doses at four hour intervals, or a total of 800 cc. of serum given within the first sixteen hours of treatment. This is the highest dosage that has come to the attention of the writers. Even this may safely be exceeded in the treatment of urgent cases.

Dosage Forms Available—Anti-Anthrax Serum is commonly supplied in 50 cc. double-end vials, with or without apparatus for facilitating intravenous injection. Ten cc. and 20 cc. syringes are also supplied.

Manufacturers—1, 2, 8, 17.

ANTIDYSENTERIC SERUM

Serum Antidysentericum—The N. N. R. defines this as the serum (polyvalent) of horses immunized against the Shiga bacillus, its products of growth, and other types of the dysentery bacillus. The strains or types commonly used include not only Shiga bacillus but other types known among bacteriologists as the Flexner, Y Hiss, and Strong types, so named for the investigator who first isolated and studied them. It is an antibacterial serum, but also contains antitoxin against the poisons elaborated by the Shiga strain of *B. dysenteriæ*.

Preparation—Cultures of the different strains of the dysentery bacillus are mixed in certain proportions, usually with the Shiga strain predominating. These mixed strains are killed and further prepared for injection into horses. Injections, first with the killed mixed cultures and finally with living organisms, are carried out on a gradually increasing scale until tests show that the titer of the serum has reached the required level. The horses are then bled at intervals. The serum is collected, sterilized by filtering, and preservative added. It is finally filled into market containers, after satisfactory sterility and potency tests.

Uses—Used in the treatment of bacillary dysentery. Cases in the early acute stages are especially suitable for serum treatment. Chronic cases and recurrent forms do not, as a rule, respond so favorably. According to Kolmer, most observers agree that a potent serum will reduce mortality of acute cases at least from 30 to 50 per cent. Its curative effect is manifest in the reduction of the number of stools, disappearance of blood and pus from the discharges, relief of pain and tenesmus, and in return of temperature to normal. The polyvalent serum is recommended for use in all cases, with a realization of the fact that infections due to certain of the strains, principally the Shiga bacillus, respond more favorably than do others. Statistics show that this serum is of value as a preventive. Its prophylactic use is justified as a means of controlling local outbreaks as in schools, institutions, camps, etc., even though the passive immunization is of short duration.

Dose—In light cases, 20 to 40 cc. are usually sufficient for prompt relief. If symptoms persist, the dosage is repeated within twenty-four hours. In severe cases, 50 to 100 cc. should be given as the initial dose and a similar amount given within twenty-four hours. Injections in milder cases are usually given subcutaneously. Better results would doubtless attend the intravenous use of the serum in the treatment of severe infections. The prophylactic or preventive use, and temporary passive immunity of perhaps two weeks duration, may be attempted by administering 10 cc. of the serum subcutaneously.

Dosage Forms Available—Commonly supplied in 10 cc. or 20 cc. syringes and in 50 cc. vials.

Manufacturers—1, 2, 17.

ANTIMENINGOCOCCIC SERUM

Serum Antimeningococcicum—A polyvalent serum containing antibodies for the various types or strains of meningococci associated with cerebrospinal meningitis.

Preparation—Cultures of a number of strains representing the four different types of the meningococcus are mixed in one emulsion. Horses are given regularly graduated doses of

this suspension at fixed intervals, until trial bleedings show that the serum of the horse is equal in agglutinin content to that of a standard control serum prepared by the U. S. Hygienic Laboratory. Then regular bleedings are made and the serum is recovered, sterilized, tested and filled into market containers in the usual way. Since the antigens used in immunizing the horses contain representative strains from each of the four principal types of meningococcus, the resulting serum contains antibodies specific for the four types and the serum is therefore described as polyvalent.

Uses—Specific in the treatment of meningococcus meningitis. In the first or carrier stage the germs are found in the mucous membranes of the nose and tonsils and in the sinuses. Treatment in this, the initial stage, is almost entirely local.

In the second stage of the disease, that is, in septic cases, there is a blood stream infection. This occurs before the meninges are affected. Sterilization of the blood stream is attempted at once by giving large doses of Antimeningococcic Serum, preferably by vein. Intravenous use is also advisable when the meningococci persist or reappear in the blood during the third stage, that is, after the localization of the infection in the membranes of the brain and spinal cord, but the precaution must be taken to desensitize the patient before giving the first intravenous injection after intraspinal injection has been done. Treatment of the third stage requires the introduction of the serum into the spinal canal. This is done by lumbar puncture. Directions for making lumbar puncture and introducing the serum intraspinally usually accompany packages of Antimeningitis Serum. In infants, if the fontanel is not closed, it is often practical and advisable to introduce the serum by intraventricular injection.

Dose—In acute meningitis it should be the rule to inject the serum into the spinal canal as quickly as possible and to maintain concentration of the serum within the canal by repeated injections. On the basis of clinical experience intraspinal dosage has been outlined according to the age of the patient, as follows: one to five years, 5 to 15 cc.; five to ten years, 10 to 20 cc.; ten to twenty years, 20 to 30 cc.; twenty years and over, 30 cc. This is a rather arbitrary statement, not to be followed blindly. The dosage varies with different patients of the same age and "the volume of serum introduced should never be greater or as great as the amount of cerebrospinal fluid withdrawn". In the presence of the milder symptoms intraspinal injections at twenty-four hour intervals for three or four days will usually bring the infection under control. In the more severe cases injections are given at eight to twelve hour intervals until the appearance of the spinal fluid and a decrease in the number of organisms found in it indicate that the infection is under control.

Dosage Forms Available—Commonly supplied in vials of 15 and 30 cc., with or without attachments for intraspinal administration.

Manufacturers—1, 2, 17, 52, 63.

ANTIPNEUMOCOCCIC SERUM

Serum Antipneumococcicum—The serum obtained from horses immunized by the injection of virulent pneumococci. There are three fixed types or strains of the pneumococcus and a fourth group of miscellaneous forms.

Anti-serums can be produced against each of the three fixed types. Moreover, they may be produced in the same horse. In this way polyvalent serums are prepared. The Type I anti-serum has been best worked out and is the one which is generally recognized. Type II serums have been produced but it is admittedly difficult to obtain a satisfactory Type III anti-serum. While some manufacturers have produced and supplied a polyvalent serum with the idea that Type II and Type III pneumonias should be given whatever benefit may be derived from such a source, yet the Type I serum only has received recognition in the N. N. R. The following applies only to the Type I serum.

Preparation—From cultures of the Type I pneumococcus standard suspensions are prepared and horses are injected with gradually increasing doses. When the blood shows satisfactory antibody content large quantities are collected and the serum is separated and treated in the usual way. It is standardized for potency by a so-called protection test, that is, by demonstrating its power to protect white mice against living cultures of virulent pneumococci.

Uses—Used in the treatment of pneumonia due to the Type I pneumococcus. Approximately one-third of pneumonia cases are Type I pneumonias, and therefore suitable for the use of Antipneumococcic Serum, Type I. The serum is highly specific and is without beneficial effect in Type II and Type III or in the group IV infections. Best results are attained by giving the serum as early as possible, and by vein. If intravenous injection is not practicable, as in very young children or in obese patients, intramuscular injection is the next procedure. Subcutaneous injection is not recommended.

Dose—An initial dose of 50 to 100 cc. of the serum, intravenously, as soon as possible after diagnosis, and a repetition of this dose every eight hours until fall of temperature and relief of symptoms indicate the control of the infection.

Dosage Forms Available—Commonly supplied in 50 cc. and 100 cc. vials.

Manufacturers—1, 2, 17, 52, 63.

ANTISTREPTOCOCCIC SERUM

Serum Antistreptococcicum—A polyvalent serum obtained by immunizing horses to several virulent strains of hemolytic streptococci, beginning first with the injection of killed cultures, followed by living streptococci. The agglutinin content of the serum offers a ready means of standardization. A potent serum also contains protective antibodies and some antitoxic substances.

Uses—Has been used in the treatment of streptococcus infections of the blood stream (septicemia). Of value in surgical septicemia and postabortal septicemia and that following streptococcus infections of wounds and minor injuries; also used to some extent in the treatment of puerperal sepsis due to the streptococcus. Erysipelas is another disease of streptococcus origin in which Antistreptococcic Serum Polyvalent has been used with some benefit in a certain percentage of cases. Recent research work, however, indicates that the streptococci of erysipelas constitute a rather distinct strain and points to the possibility of the development of a more specific serum or antitoxin.

Dose—The importance of early administration is emphasized and the use of large doses given intramuscularly or preferably by intravenous injection. The initial intravenous dose is 30 to 100 cc. of the serum for adults. If no improvement results, or if acute symptoms again appear after temporary improvement, the second and subsequent doses should be given intravenously at six to twenty-four hour intervals. If improvement follows the first dose, subsequent doses may be given intramuscularly or subcutaneously.

Dosage Forms Available—Commonly supplied in 10 cc. and 20 cc. syringes, and in 20 cc., 30 cc., 50 cc., and 100 cc. vials.

Manufacturers—1, 2, 8, 17, 52, 56, 63.

ANTIGONOCOCCIC SERUM

License has been issued by the U. S. Public Health Service for the preparation of Antigonococcic Serum. The evidence of its therapeutic value has not yet been considered sufficient to admit it to the N. N. R. It is prepared from serum of horses immunized to different strains of gonococci, and has been used to some extent in the treatment of acute gonorrheal complications, *e.g.*, gonorrheal epididymitis and gonorrheal arthritis.

Dosage Forms Available—Commonly supplied in 2 cc., 10 cc., 12 cc., 50 cc., and 100 cc. containers.

Manufacturers—1, 2, 17, 52.

NORMAL HORSE SERUM

Serum Equinum—Although not a specific immunizing product, Normal Horse Serum may conveniently be placed in the general group of the serums. Normal Horse Serum is that separated from the freshly drawn blood of normal horses and sterilized by filtration. It is called normal serum because it contains no antibodies or antitoxins produced artificially by the injection of antigens into the horse. It is therefore to be distinguished from the curative serums which contain antitoxins, or antibacterial bodies, or both.

Uses—Its principal use is to increase the coagulability of the blood and is employed in the treatment of hemophilia and other hemorrhagic conditions, for example, hemorrhages following wounds and fractures and during or following surgical operations. It has also been used in non-specific protein therapy. Like other foreign proteins, injected hypodermically, sufficient doses of Normal Horse Serum are followed by a shock reaction, which has been considered of benefit in the treatment of many conditions.

Dose—May be applied locally to any bleeding surface by means of sterile cotton saturated with the serum. It is recommended for use subcutaneously in doses of 20 to 30 cc., or intravenously in doses of 10 to 20 cc., as a means of increasing coagulability of the blood and of preventing hemorrhage.

Dosage Forms Available—Commonly supplied in 10 cc. syringes or ampuls, in 20 cc. syringes or vials, in 25 cc., 50 cc., and 100 cc. ampuls, in 30 cc. and 50 cc. vials, and in 50 cc. and 100 cc. bottles.

Manufacturers—1, 2, 6, 8, 14, 17, 52, 56, 63, 65.

Antibody Solutions

Under this heading is placed a therapeutic agent of comparatively recent development. Separate classification, to distinguish it from either antitoxins or antibacterial serums, is given because it is practically free from serum proteins. The method of preparation and the nature of the resulting product make it clear that it is not a serum nor an antitoxin, but in fact a solution of antibodies.

PNEUMOCOCCUS ANTIBODY SOLUTION

An aqueous solution of the protective antibodies specific for the pneumococcus, Types I, II, and III, practically free from chemically demonstrable proteins of horse serum.

Preparation—Since the time of Ehrlich and Morganroth (1899), it has been known that bacteria absorb their specific antibodies from an immune serum. The bacteria in turn can be washed free from the serum, yet they will carry with them quantities of the absorbed immune antibodies. The preparation of Pneumococcus Antibody Solution depends upon these facts and upon the further discovery that it is possible to separate or dissociate the protective antibodies from the pneumococcus. Suspensions of pneumococci of the three fixed types are treated with potent antipneumococcic serum. The bacteria are then washed free from the serum, and the pneumococci treated so that the protective antibodies are separated from the bacterial cells and obtained in relatively pure state in isotonic salt solution. It is sterilized by filtration and the finished product is a perfectly clear colorless solution.

Uses—There is evidence that this antibody solution is a specific agent of value in the treatment of lobar pneumonia. Records show that it is of particular benefit in the Type I cases. In Type II cases, given early and in large doses, it checks the pneumonia and prevents the septicemia to which Type II is particularly prone. It is only occasionally effective in Type III pneumonias. Since group IV cases are not caused by the fixed types, beneficial effects are not often noted. Since 95 per cent of the cases of lobar pneumonia are pneumococcus pneumonias, and since Type III cases constitute less than 10 per cent of the total, it has been recommended that Antibody Solution be given immediately upon diagnosis of lobar pneumonia. It should not be withheld to await a laboratory report on the type of the causative organism. This recommendation is also based upon observations that Antibody Solution, like serums and antitoxins, gives the best results when administered early in the disease. Time is a very important factor in the specific treatment of pneumonia and the use of Antibody Solution, if instituted during the first, second, or third days of the disease, has given much better results than when first administered during the fourth day or later.

Dose—Pneumococcus Antibody Solution is administered preferably by the intravenous route, in doses of from 25 to 100 cc., repeated at intervals of six to twelve hours if necessary. Sometimes a "thermal reaction", *i.e.*, a chill and further rise of temperature of one or two degrees, may follow shortly after intravenous administration. This reaction passes over within a very short time and is usually followed by rapid lowering of the temperature and prompt improvement in other symptoms. Reactions are not considered dangerous except in the presence of kidney or heart lesions, and are regarded by some as of value in treatment. However, progress has been made in eliminating the thermal reactions without reducing the therapeutic efficiency of the preparation for the fixed types. Subcutaneous administration, although apparently of benefit in some instances, is not recommended. Published statistics indicate that, given by this method, the solution is of little benefit. On the other hand, it has been shown that, when Pneumococcus Antibody Solution is given intravenously, protective antibodies can be demonstrated in the circulating blood immediately and have been found to persist there for a variable period of two weeks or longer.

Dosage Forms Available—Supplied in 50 cc. vials.

Manufacturer—2.

CHAPTER CXX

BIOLOGICAL PRODUCTS USED FOR ACTIVE IMMUNIZATION

Following recovery from many of the acute infections, such as scarlet fever, typhoid fever, and others, a more or less well-developed and lasting immunity appears. This is a matter of common knowledge. The condition represents an acquired active immunity resulting from the stimulation of the body cells by the infecting agent and the excess production of specific antibodies. But in this chapter we are interested in the possibility of *protection without infection*, that is, the artificial production of an active immunity without subjecting the individual to the disease itself. Such use for biological products follows from the early observations on vaccination against smallpox and against rabies. Jenner's observations and experiments proving (1798) that cowpox virus or vaccinia, inoculated into the human subject, gave immunity to smallpox, was followed some eighty years later by the accidental discovery by Pasteur that a disease virus or germ could be so modified or attenuated that its inoculation into the human subject did not cause the actual disease, yet it would stimulate the body cells to produce specific antibodies and thus give rise to active immunity. Upon this fundamental observation the whole theory and practice of prophylactic immunization has been built. Pasteur himself early devised a method of attenuating the virus of rabies or hydrophobia and a method of immunizing against this disease.

The historical importance of smallpox vaccine and of rabies vaccine and the effective immunity induced by them gives them first place in the discussion of biological products used for active immunization.

The Viruses in Living Attenuated Form and Killed Viruses

VACCINUM VARIOLÆ. U. S. Smallpox Vaccine

[**Vaccin. Var.**—Virus Vaccinicum U. S. P. IX, Glycerinated Vaccine Virus, Jennerian Vaccine]

Smallpox Vaccine consists of a glycerinated suspension of the vesicles of vaccinia or cowpox which have been obtained from healthy vaccinated animals of the bovine species (see Fig. 789). The vesicles must be removed and the vaccine must be prepared under aseptic conditions.

The vesicles (see Fig. 790) must be removed from the animal at the time of maximum potency, thoroughly triturated and made into a smooth suspension with an aqueous solution of glycerin. This solution shall not be acid to bromcresol purple T.S. or distinctly alkaline to phenol red T.S.

The following regulations established by the Pharmacopœia conform to those issued by the U. S. Public Health Service. Smallpox Vaccine must be prepared in an establishment licensed by the Secretary of the Treasury of the United States. The following precautions must be observed in licensed establishments:

No vaccine shall be used from any animal having a communicable disease, other than vaccinia. Animals used for propagating Smallpox Vaccine must have been previously subjected to a tuberculin test and must have been held at least seven days in quarantine under daily veterinary inspection prior to vaccination. After the vaccine pulp is removed from each animal, a necropsy shall be performed, permanent records of which shall be kept. Each lot of

Smallpox Vaccine shall be examined to determine its freedom from undue bacterial content and a special examination shall be made of each lot to determine the absence of tetanus organisms and other pathogenic anaërobes.

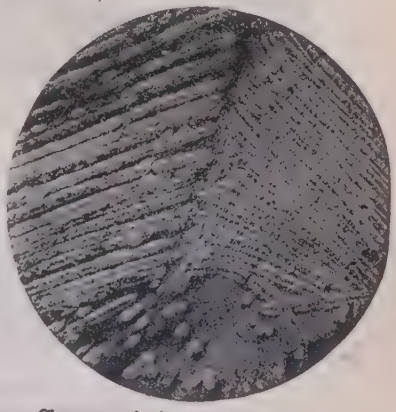
FIG. 789

Vaccinating calf. Light scarifications are made on a shaved and thoroughly cleansed area of the skin of the abdomen. Seed vaccine is then applied. Note precautions taken by operator to prevent contamination.

Permanent records must be kept of these examinations. The finished product must be placed in sterile containers that comply with the requirements of the law and of the regulations established by the United States Public Health Service.

Smallpox Vaccine loses potency rapidly, even at moderate temperatures. It must, therefore, be kept at the lowest possible temperature, preferably below 0° C., and never above 5° C.

FIG. 790



Close-up of the vaccine vesicles which develop on skin of the calf. Pulp or lymph from these vesicles is removed by a curette, with precautions against contamination

Uses—Smallpox vaccine has amply demonstrated its efficacy in producing an effective immunity against smallpox. Human beings of both sexes and of all ages and races are very susceptible to smallpox, and it has been chiefly through the widespread use of vaccination that the deaths from the disease have been reduced as much as they have, and that the epidemics of olden times, which used to assume the nature of a plague, have ceased to appear. The statistical evidence from human experience is supported by the experiments conducted with great care both in England and in America, in which it was shown that smallpox vaccine will produce an immunity in monkeys which will protect them against subsequent infection with a virulent smallpox

virus. The extremely rigid scientific control over every step in the modern methods of producing smallpox vaccine, and the precautions which are taken to make sure that the finished product is free from pathogenic or harmful germs, has contributed greatly to the safety of the practice, so that untoward results following vaccination have, in recent years, been conspicuous by their absence.

The dosage requires no discussion since the process of vaccination consists of applying a tiny quantity of the vaccine to a light scarification, abrasion, or shallow puncture of the skin. For the technic of vaccination and interpretation of the results, readers are referred to the publications of the U. S. Public Health Service, to standard textbooks, and to direction circulars which accompany the trade packages.

Dosage Forms Available—Supplied in hermetically sealed capillary tubes and in combination capillary tube and scarifying point (Tube-Point). May be obtained in packages of 1, 2, 3, 5, and 10 vaccinations.

Manufacturers—1, 2, 6, 8, 14, 17, 52, 56, 63 and 64.

Pulp, removed from vesicles shown in Fig. 790, is being ground in glycerin to produce a smooth homogeneous suspension

Unofficial Viruses

SMALLPOX VACCINE—DRIED

Many attempts have been made to prepare a smallpox vaccine which would withstand the effects of higher temperatures and one that would be suitable for shipment to, and use in, tropical and sub-tropical countries. A dried smallpox vaccine for such use has been supplied for some time by two or more European laboratories. Dried Smallpox Vaccine was successfully produced on a manufacturing scale in the United States as early as 1922, and has found a considerable field of usefulness in torrid countries. License for its regular production was issued by the U. S. Public Health Service in 1925, but it is supplied chiefly in export trade to those regions of the world where the temperature conditions or lack of refrigeration facilities render the use of the glycerinized vaccine virus impractical.

Manufacturer—2.

RABIES VACCINE

[Vaccinum Rabies—ANTIRABIC VACCINE]

Rabies is an acute infectious disease caused by a filterable virus It is one of the diseases most dreaded by the laity. The virus or causative agent is contained in the saliva of the rabid animal. Infection takes place through abrasions or punctures of the skin following bites or scratches. The virus shows a special affinity for the nervous system and makes its way along the nerve tracts to the central nervous system, the involvement of which causes the distressing symptoms. Fortunately, the incubation period is a long one, varying from

fourteen to ninety days, and it is possible to develop a protective immunity before the symptoms of the disease appear. Pasteur was the first to demonstrate the protective value of Rabies Vaccine. The method which he devised is still in common use with some modifications.

Preparation—Rabies Vaccine is attenuated or rendered practically non-virulent for man by repeated passage through rabbits, and is treated in various ways to decrease or destroy infectivity. The method of preparing Rabies Vaccine by the Pasteur method, as modified by the U. S. Hygienic Laboratory, is outlined briefly in the N. N. R. as follows: The spinal cords of infected rabbits are dried over caustic potash at constant temperature for from one to eight days, then cut into 0.5 cm. pieces and preserved in glycerin. For use, one of these pieces is emulsified in physiological solution of sodium chloride and injected into the subcutaneous tissue of the anterior abdominal wall. Injections are continued daily for twenty-one days.

There are other methods of treating the virus before inoculation. These are (a) the dilution method—Högyes, (b) low temperature method—Harris, (c) dialyzing method—Cummings, (d) phenol treated or killed virus—Semple and Fermi.

In the dilution method of Högyes, the brains of rabbits dead from rabies are preserved in glycerin. Emulsions of the brain substance are prepared, beginning with a 1 in 20,000 dilution and increasing the strength until a 1 in 100 dilution is given. The Harris low-temperature method involves freezing the emulsion of the brains and spinal cords and desiccation in vacuum. The result is a dried powder which is standardized, and emulsions in graded doses are prepared for injection. The method of dialysis, or Cummings' method, is applied by dialyzing a 1 per cent suspension of brain tissues against running distilled water until the active virulent virus is destroyed.

The phenol killed virus, Semple and Fermi, calls for a preparation of an emulsion or standard suspension of the brain and cord substance killed by treatment with phenol.

Uses—Rabies Vaccine is used to establish an immunity to rabies or hydrophobia by treating the individual after the bite of a rabid animal, but before the incubation period is completed. The injection of attenuated, or modified, or killed virus during the period of incubation stimulates the production of antibodies, so that the infecting virus of the wound is neutralized or destroyed. The efficacy of rabies vaccine is demonstrated by the statistics which indicate the reduction in the death rate from 16 to 20 per cent to less than one-half of 1 per cent (0.5 per cent). The immunizing treatment, to be effective, must be instituted as soon as possible after the bite has been inflicted. The treatment is without effect after the symptoms of rabies have appeared. The resulting immunity is not regarded as very durable and the recommendation is that if the person is bitten a second time by a rabid animal one or more years after an immunizing treatment, a complete series of prophylactic injections should be repeated.

Dose—Dosage recommendations vary considerably, according to the method of preparation and the amount and condition of the virus in the suspension injected. Rabies Vaccine, Pasteur, as prepared in accordance with the general method of the U. S. Public Health Service, consists of 21 to 25 doses. The doses are graded so that the first contains virus of the greatest attenuation, while the last dose in the series represents the highest. Doses are injected at 24 hour intervals. Rabies Vaccine prepared by the dilution method (Högyes) is supplied in a treatment of 18 doses, each dose varying in quantity from 3 to 5 cc., the first one consisting of a 1 in 20,000 dilution and the last a 1 in 100 dilution. Rabies Vaccine (Harris) is given in daily doses over a period of 10 days or more, the dosage increasing gradually up to a maximum at the tenth day, which may be supplemented if desired. Rabies Vaccine (Cumming's method) is available in 14 or 21 dose treatments. The 21 dose is recommended for the more severe cases, the 14 dose in the less severe. A 2 cc. dose is given each day. Rabies Vaccine, phenol killed, is available in 14-dose treatment packages. It possesses better keeping qualities than the attenuated living virus, and therefore can be stocked by pharmacists, and the entire treatment can be put up and dispensed in one package. The doses are the same size and strength, which avoids the necessity of following out a fixed schedule of increasing doses.

Manufacturers—*Rabies Vaccine, Pasteur* (U. S. modification), 2, 8, 14, 17, 49, 52 and 63.
Rabies Vaccine (Högyes), 50, 54.
Rabies Vaccine (Harris), 56, 66.
Rabies Vaccine (Cummings), 1.
Rabies Vaccine, phenol killed, 2, 84, 85.

TOXINS; TOXIN-ANTITOXIN MIXTURES; TOXOIDS

Under this heading we include the Scarlet Fever Streptococcus Toxin, Diphtheria Toxin-Antitoxin Mixture and Diphtheria Toxoid. It will be noted that these are preparations of the soluble exotoxins, or a modified form thereof. The organisms which produce these toxins are not used for immunizing purposes.

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE

The toxin produced by the diphtheria bacillus is exceedingly powerful and very small amounts will produce symptoms of poisoning and even death. It is not practical, therefore, to use this toxin for the production of active immunity. Early in the history of the production of Diphtheria Antitoxin, it was found that the horses could be more quickly immunized, and with greater safety if they were given injections of a mixture of toxin and antitoxin. The presence of antitoxin in the injected material protected the animal against untoward effects, yet active immunity developed promptly. This is explained on the assumption that the toxin was gradually separated or dissociated from the mixture and acted as an immunity stimulant on the body cells. The early observation on animals naturally led to the suggestion that the same method could be used to produce immunity in man. Von Behring and others demonstrated the safety of the method for human beings and thus paved the way for the general adoption of the method. A great deal of evidence has accumulated which demonstrates, beyond a doubt, that injections of toxin-antitoxin mixture are effective in developing an active immunity to diphtheria in persons susceptible to diphtheria. One of the most important contributions to the subject is that of Dr. William H. Park and his co-workers of the New York State Department of Health, who have greatly increased the safety of the procedure. They experimented with toxin-antitoxin mixtures of different strengths and found that what is known as the "1/10 L plus dose" was effective, although containing only 1/30 as much toxin as some of the older preparations in use. As a result, the older preparations of 3 L plus or 5 L plus doses have been discontinued. Practically the only preparations available commercially are of the 1/10 L plus strength.

Preparation—The well-ripened toxin of known strength is thoroughly mixed with a carefully determined amount of concentrated antitoxin. The measurement of the quantity used requires extreme care, and the resulting mixture must be subjected to elaborate tests on guinea pigs, not only to insure sterility but to determine its toxicity, that is, whether a sufficient degree of neutralization has been effected. The 1 cc. dose employed in human immunization is so low in toxicity that it will not kill a guinea pig.

Uses—Toxin-Antitoxin Mixture is effective in stimulating immunity to diphtheria. Since susceptibility to this disease is greatest between the ages of two and ten years, the greatest field of usefulness is in the immunization of children, especially inmates of children's homes and asylums, and in the protection of children of pre-school age, and especially against the dangers of infection during the school years.

Dose—Doses of 1 cc., given subcutaneously and repeated at weekly intervals until three doses have been given. In children of one year the volume is reduced one-half with each injection. From 5 to 8 per cent are so highly susceptible to diphtheria that three injections are not sufficient to produce the desired degree of immunity. Such individuals require additional doses of the mixture in order to render them immune. The reactions to the injections in young children are practically negligible. In children of school age there may be some soreness and slight temperature. Adults and older children may develop considerable local reaction. Immunity develops rather slowly and does not reach its height until three to six months following the injections. According to the records it is evident that immunity persists for several years and possibly for life.

Dosage Forms Available—Commonly marketed in vials, ampuls, or syringes of 1 cc. each, three doses to the package; or, for convenience in hospital and institutional work, it may be obtained in ampuls or vials of 10 cc., 20 cc., and 30 cc.

Manufacturers—1, 2, 8, 14, 17, 52, 56, 63, 64, 65.

DIPHTHERIA TOXOID

Diphtheria Toxoid is a diphtheria toxin, so modified that it has lost most, if not all, its toxicity for guinea pigs, yet its antigenic or immunity-stimulating properties remain. A strong toxin is obtained from a culture of the diphtheria bacillus and is then treated with formaldehyde until five doses of the size ordinarily used on the human being will cause no symptoms of acute poisoning, when injected subcutaneously in guinea pigs. Some evidence has accumulated which shows that such a modified toxin is of considerable utility as an immunizing agent. It has the advantage over Toxin-Antitoxin Mixture of being less toxic, and containing no horse serum, but considerable work remains to be done in perfecting methods of preparing a uniformly potent preparation and in the accumulation of evidence of its immunizing power. At this writing the U. S. Public Health Service has issued tentative specifications for Diphtheria Toxoid, and has under consideration the releasing of the product for the market.

SCARLET FEVER STREPTOCOCCUS TOXIN

An approved product, now made generally available for the development of active immunity to scarlet fever. It was developed by Drs. G. F. and G. H. Dick, and is now issued under license from the U. S Public Health Service and the Scarlet Fever Committee, Inc. This toxin is prepared from cultures of scarlet fever streptococci, and standardized by comparison with an official toxin distributed by the U. S. Public Health Service. It is used as an immunizing agent to develop an active immunity to scarlet fever and is of value in immunizing susceptible individuals.

Dose—The dosage recommended consists of five injections of 1 cc. each. Doses are of graded strength, beginning with 500 skin test doses per cc. and increasing up to 20,000 skin test doses. The injections are given subcutaneously at weekly intervals, and the resulting immunity reaches its height within three weeks after the last dose.

Dosage Forms Available—Marketed in packages of five doses in 1 cc. containers, and in larger packages for hospital and Board of Health use.

Manufacturers—2, 52.

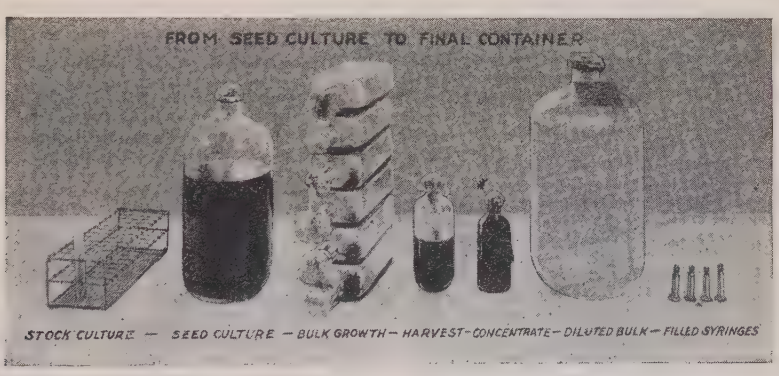
BACTERIAL VACCINES

Bacterial vaccines, or bacterins, are sterile standardized suspensions of bacteria in physiological salt solution. Ordinarily, some preservative is added, such as tricresol, phenol or glycerin. When injected into the body, the bacterial substance tends to stimulate the tissues to the production of antibodies.

Preparation—The preparation of bacterial vaccines demands careful technic and the experience of trained bacteriologists. The first step is to procure the infecting agent or causative organism in pure culture. These may be isolated from pus collected from an abscess or sinus, or they may be taken from nasal secretion, or from sputum, or from urine, or blood, or direct from an infected lung, etc.

When this is done, the isolated strains may then be maintained as "stock cultures". In the preparation of a vaccine, the stock culture is used as the source or "seed". The organisms are planted in suitable media and grown under optimum conditions. After a suitable interval at controlled temperature the growth is collected and emulsified. Purity tests are made to determine

FIG. 792



FROM SEED CULTURE TO FINAL CONTAINER
STOCK CULTURE — SEED CULTURE — BULK GROWTH — HARVEST-CONCENTRATE — DILUTED BULK — FILLED SYRINGES

Illustrating steps in the process of making bacterial vaccine

that the suspension contains none but the desired organism. If this test is satisfactory the suspension is killed by exposure to heat or by other means. The killing temperature is carefully controlled, the degree and time of exposure varying for different types of vaccines. A preservative is then added and the vaccines standardized by bacterial count and dilution to the required strength, placed in the final containers and released for distribution only after satisfactory tests show the product to be sterile.

Uses—As antigens capable of producing active immunity, some of the bacterial vaccines have proved of great value in prophylaxis. The preventive use of typhoid bacillus vaccine is the outstanding example. Pneumonia, plague, cholera and pertussis vaccines have also been so used.

Their employment in the treatment of disease has been extensive, not only in chronic infectious diseases, but even in the acute stages. No general statement can be made of their value in this connection, except that subacute and chronic cases seem to be more amenable to treatment. Some have apparently given much more favorable results than others. Specific indications are mentioned under the individual products following.

Dose—For prophylactic (preventive) immunization, three to five gradually increasing doses are given at intervals of three to seven days.

For treatment of acute conditions, no scheme of dosage can be stated definitely, for the reason that no two individuals react alike to the same dose of a given bacterin, and because reactions produced by different bacterins are not the same, owing to inherent differences in the germs themselves. The initial dose is arbitrarily selected, the physician being guided by the thought that, in general, the severer the disease the smaller the first dose. Subsequent doses are controlled as to amount and interval by the results obtained from preceding doses. The clinical symptoms which physicians look for in controlling dosage of bacterial vaccines have been summarized as follows:

A *sub-minimal* dose has no perceptible effect.

A *minimal* dose is rapidly followed by a feeling of well-being on the part of the patient, and a transient fall in temperature, if in a febrile case.

A *medium* dose may induce some local reaction at the site of injection and a slight reaction at the focus of infection, and possibly a slight general reaction which may show itself by a rise of temperature of not more than 1° C, accompanied by a slight malaise and some increase in pulse rate. This is followed, in twenty-four hours, by a fall in temperature and a general improvement in the condition.

A *large* dose is followed by a local reaction and by a severe reaction at the focus of infection, and symptoms of a general reaction (malaise, rise of temperature, etc.) may persist for some time without evidence of improvement.[1]

ACNE BACILLUS VACCINE—Acne Bacterin. Prepared from the acne bacillus. Used in cases of acne vulgaris, especially in the cystic form and in acne indurata. Even when other therapeutic measures are regarded as more important, Acne Vaccine may still be given as a supplementary treatment to improve the patient's immunity to the acne bacillus.

Dose—Five to fifty million killed acne bacilli, as initial injection.

Dosage Forms Available—Commonly supplied in packages of four vials or syringes, and in graded doses; and in bulk packages of 5 cc., 10 cc., and 20 cc. vials.

Manufacturers—1, 2, 8, 17, 30, 43, 45, 52, 56, 63, 65, 86.

CHOLERA VACCINE, CHOLERA BACTERIN—Prepared from killed cholera vibrios.

Indications—Preventive immunization against Asiatic cholera.

Dose—Three injections at ten-day intervals.

Dosage Forms Available—In packages of three syringes each, the first of 500 million and the second and third each containing 1000 million killed cholera vibrios; and in packages of two 1 cc. vials, containing respectively, 4000 and 8000 million killed cholera vibrios; also in packages of two 10 cc. vials, containing respectively, 4000 and 8000 million cholera vibrios per cc.

Manufacturers—2, 17.

COLON BACILLUS VACCINE—Coli Bacterin. Prepared from killed Bacillus Coli. Used in infections caused by this organism, such as cystitis, catarrhal jaundice, etc. Initial dose, 10 to 50 million B. coli.

Dosage Forms Available—Packages of four syringes or four ampuls of graded doses, and in 5 cc., 10 cc., and 20 cc. vials.

Manufacturers—1, 2, 6, 8, 17, 30, 43, 45, 51, 52, 56, 58, 65, 67, 79, 86.

MENINGOCOCCUS VACCINE—Meningococcus Bacterin. Prepared from various strains of the meningococcus. Used in preventive immunization against cerebrospinal meningitis.

Dose—Three injections of 1000, 2000 and 2000, or 500, 1000 and 1000, million killed meningococci.

Dosage Forms Available—Packages of four syringes, four ampuls, three syringes or three ampuls of graded doses, and in 5 cc., 10 cc., 12½ cc., and 20 cc. vials.

Manufacturers—1, 2, 17, 30, 52, 56.

GONOCOCCUS VACCINE—Neisser Bacterin. Prepared from strains of the gonococcus. Used in gonorrhea and in gonorrheal rheumatism, etc. Initial dose, 10 to 50 million killed gonococci.

Dosage Forms Available—Packages of four syringes, four ampuls, or four vials of graded doses, and in 5 cc., 10 cc., 12½ cc. and 20 cc. vials.

Manufacturers—1, 2, 6, 8, 14, 17, 30, 45, 51, 52, 56, 58, 63, 65, 79, 86.

---

[1] After Fleming and Clemenger, "Nelson's Loose Leaf Medicine".

PERTUSSIS VACCINE—Pertussis Bacterin. Prepared from strains of the pertussis bacilli isolated from cases of whooping cough. Used in the treatment and preventive immunization of whooping cough (pertussis). Initial dose, 250 million killed pertussis bacilli. For children more than one year old, the initial dose should be 500 million. Increased doses should be given every second day as follows: 500, 1000, 2000, 4000 and, if necessary, as much as 10,000 million. For immunity three doses are given of 500, 1000 and 2000 million organisms at three day intervals.

Dosage Forms Available—Packages of four syringes, four ampuls, four bulbs or four vials, and in packages of three syringes, three ampuls or three vials of graded dosage, and in 5 cc., 10 cc., 12½ cc. and 20 cc. vials.

Manufacturers—1, 2, 8, 14, 17, 30, 43, 45, 52, 56, 58, 63, 65.

PLAGUE VACCINE, PLAGUE BACTERIN—Prepared from the bacillus pestis. Used in prevention of bubonic plague. Initial dose, 1000 million to 5000 million killed plague bacilli.

Dosage Forms Available—In single vaccination, double vaccination, and triple vaccination packages, and in 1 cc. vials and 20 cc. vials.

Manufacturers—2, 17, 56.

PNEUMOCOCCUS ANTIGEN—MODIFIED—A vaccine or "antigen" prepared by digesting a suspension of pneumococci of the three fixed types and Group IV strains until about 95 per cent of the organisms become Gram-negative and preparation is relatively non-toxic to guinea pigs. It is not intended for prophylactic use, but there is some evidence that it is of value in the treatment of lobar pneumonia.

Dosage Forms Available—Marketed in 5 cc. vials, 20 million partially autolyzed pneumococci per cc.

Manufacturer—56.

PNEUMOCOCCUS VACCINE—Pneumococcus Bacterin. Prepared from killed pneumococci of the various types is of considerable value as a prophylactic for the prevention of pneumonia, but of doubtful value in treatment.

Dosage Forms Available—Packages of four syringes, four ampuls, and four bulbs and three syringes or three vials of graded doses, and in 5 cc., 10 cc., and 20 cc. vials.

Manufacturers—1, 2, 8, 14, 17, 30, 43, 45, 51, 52, 56, 58, 63, 65, 67, 79, 86.

FIG. 793

Large incubator room where constant temperature of 37° C. is maintained to promote growth of quantities of bacterial organisms for the production of bacterial vaccines

STAPHYLOCOCCUS VACCINE—Staphylococcus Bacterin. Usually consists of a suspension containing both the *aureus* and *albus* strains of the staphylococcus. Some contain also the *citreus* strain.

Uses—Used in the treatment of boils, carbuncles, in certain cases of acne and in sycosis.

Dose—Initial dose, 50 to 250 million killed staphylococci.

Dosage Forms Available—Packages of four syringes, four ampuls or four vials in graded doses, and in 5 cc., 10 cc., and 20 cc. vials.

Manufacturers—1, 2, 6, 8, 14, 17, 30, 43, 45, 51, 52, 56, 58, 63, 65, 67, 79, 86.

STREPTOCOCCUS VACCINE—Streptococcus Bacterin. Prepared from various strains of the streptococcus. Used in abscesses and cystitis. Has been suggested for preventive use in puerperal fever, acute rheumatism, etc. Initial dose, 10 to 50 million killed streptococci.

Dosage Forms Available—Packages of four syringes, four vials, or four bulbs of graded doses, and in 5 cc., 10 cc., 12½ cc. and 20 cc. vials.

Manufacturers—1, 2, 6, 8, 14, 17, 30, 43, 45, 51, 52, 56, 63, 65, 67, 79, 86.

TYPHOID VACCINE—Typhoid Bacterin. Prepared from the bacillus typhosus. Of recognized utility in the prevention of typhoid fever, immunity persisting in most cases for a period of two years or longer.

Dose—Initial preventive dose, 500 million killed bacteria, second and third doses containing 1000 million killed bacteria, given at intervals of seven to ten days.

Dosage Forms Available—Three-dose immunizing packages in syringes, vials or bulbs, also in four syringe and four ampul packages of graded doses, and in larger packages for hospital use. Bulk packages of five 5 cc., 10 cc. and 20 cc. vials.

Manufacturers—1, 2, 6, 8, 14, 17, 30, 43, 45, 51, 52, 56, 58, 63, 64, 65, 86.

MIXED BACTERIAL VACCINES

Mixed bacterial vaccines are made by mixing or combining suspensions of two or more species of bacteria. The formulas of the so-called mixed vaccines vary and their number is large, so that space will not permit detailed information concerning each one. Formerly, a considerable number were admitted and described in the N. N. R., but of recent years many of them have been dropped from the book on the grounds that there was not sufficient acceptable clinical evidence to warrant retaining them.

In one instance, however, a mixed vaccine has proven of very great value, and has practically supplanted the use of the single vaccine. This is the Typhoid-Paratyphoid Vaccine, or Typhoid Bacterins, Mixed.

TYPHOID VACCINE, MIXED—Typhoid Bacterin, Mixed. Triple Vaccine (TAB). This is a suspension containing the true Bacillus typhosus and the two strains of the Bacillus paratyphosus "A" and "B". The triple vaccine is now used very generally and gives protection against both the typhoid and the paratyphoid fevers.

Dose—Three injections at seven to ten day intervals.

Dosage Forms Available—Packages of three syringes, three vials, or three bulbs in graded doses, sufficient for one complete immunization; also in packages of thirty vials, sufficient for ten immunizations, and in 5 cc. and 20 cc. vials.

Manufacturers—1, 2, 6, 8, 14, 17, 30, 45, 51, 52, 56, 63, 65, 86.

OTHER MIXED VACCINES—It will be sufficient here to merely mention other mixed vaccines by name and refer the reader to the price lists of the manufacturers for information concerning the formulas. These include Acne Vaccine Combined or Mixed, Catarrhal or Respiratory Vaccines Mixed, Combined Coli Vaccine (Van Cott), Coley's Mixed (Erysipelas and Prodigiosus) Vaccine, Gonococcus Mixed Vaccine or Neisser Bacterin Mixed, Influenza-Pneumonia Vaccines, Pertussis Mixed Vaccine, Combined Streptococcus and Staphylococcus Vaccine, and Staphylococcus-Acne Vaccine.

Manufacturers—1, 2, 8, 17, 30, 52, 56, 63, and others.

SENSITIZED BACTERIAL VACCINES—SEROBACTERINS

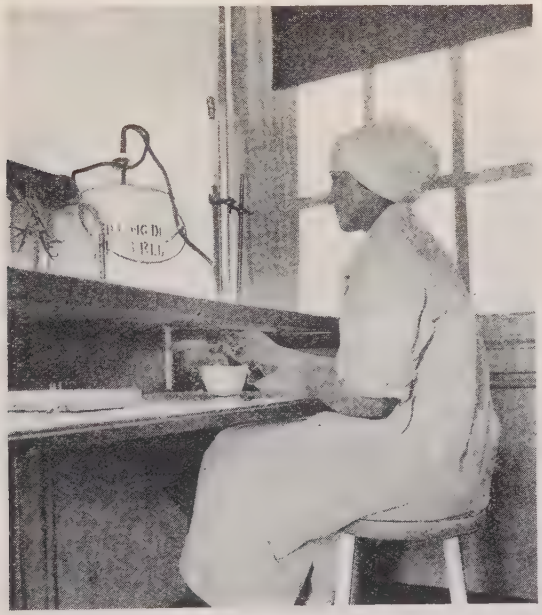
(Antigen-Antibody Combinations)

In a previous chapter, in discussing the preparation of Pneumococcus Antibody Solution, the fact was mentioned that a suspension of bacteria, treated with a specific immune serum, will absorb a considerable quantity of Antibodies. The serum can then be removed by washing, leaving the bacteria (antigens) in combination with their specific antibodies. They are then resuspended in salt solution and standardized by bacterial count. Bacteria, so treated and prepared in combination with antibodies, were first introduced by Besredka of the Pasteur Institute, Paris, and he and his followers are responsible for much of the early clinical evidence upon which the use of serobacterins is based. The descriptive term "sensitized" was also applied by Besredka, but our present conception of them is probably better conveyed by the term "antigen-antibody combinations". There is evidence that when a sensitized vaccine or serobacterin is injected into the body, a portion of the antibodies carried by the bacteria are set free in the blood stream and thus confer a certain amount of immediate protection in the nature of a passive immunity, and that this is followed in due course by the development of an active immunity in the same way as in the case of plain or unsensitized bacterial vaccines. Active immunity following injection of plain vaccines does not

begin to appear until about seven to ten days after injection. It is claimed that the sensitized vaccine gives an immediate protection which is of some value during this preliminary period before the active immunity begins to develop. Sensitized vaccines are also claimed to be less toxic and to give less uncomfortable reactions following injection.

Sensitized vaccines correspond to the plain bacterins in indications and uses, except in one point, namely, that serobacterins may be used with greater confidence during an epidemic and after exposure to infection, for the reason that they give some immediate protection. Dosage with serobacterins is considerably higher than with the plain bacterins. The process of sensitizing

FIG. 794



Filling bacterial vaccine into containers. The bacterial vaccine is passed through sterile tubing and filled into vials or syringes under a bell-glass as a precaution against accidental contamination from bacteria in the air

detoxicates the bacterial suspensions so that it is possible to administer sensitized vaccines in larger doses (two to six times the corresponding unsensitized vaccine), and to give them at shorter intervals. The following is a list of the serobacterins licensed by the U. S. Public Health Service: *Acne Serobacterin, Cholera Serobacterin, Coli Serobacterin, Meningococcus Serobacterin, Neisser Serobacterin, Pertussis Serobacterin, Pneumococcus Serobacterin, Staphylococcus Serobacterin, Streptococcus Serobacterin*, and *Typhoid Serobacterin.*

Dosage Forms Available—Practically all of the above are marketed in packages of four syringes, and in 5 cc. and 20 cc. vials. Typhoid Serobacterin Cholera and Meningococcus Serobacterin are also supplied in a three syringe immunizing package.

Mixed serobacterins are also supplied. The principal one of these is Typhoid Serobacterin Mixed, containing the typhosus and B. paratyphosus "A" and "B". Others include Acne Serobacterin Mixed, Catarrhal Sero-

bacterin Mixed, Influenza Serobacterin Mixed, Neisser Serobacterin Mixed, Pertussis Serobacterin Mixed and Pneumococcus Serobacterin Mixed, Staphylococcus Serobacterin Mixed and Staphylo-Streptococcus Serobacterin Mixed. These are marketed in packages similar to the individual serobacterins.

Manufacturer—2.

AUTOGENOUS VACCINES

In protective immunization in general, stock vaccines are used, and in most instances, notably in the case of Typhoid Vaccine, results are entirely satisfactory. In the treatment of acute infections stock vaccines are required so that time shall not be lost from treatment while awaiting the isolation and identification of the infective agent. On the other hand, in some chronic infections of long standing, it sometimes happens that after a slight initial improvement following the use of stock vaccine, the condition will remain

FIG. 795

Laboratory animals used in testing bacterial vaccines and serums to determine their freedom from contaminating pathogenic bacteria and absence of toxic property

practically stationary, in spite of repeated injections. Substitution of an autogenous vaccine is then indicated.

Autogenous vaccines are those prepared from bacteria isolated from the patient. Their use has the advantage of bringing to the patient an antigen calculated to stimulate antibodies specific for the infecting organism. Their use is indicated particularly in chronic conditions where vaccine therapy is plainly indicated and where stock vaccines have failed to bring about the desired improvement.

Manufacturers—Some of the manufacturers of bacterial vaccines are equipped to supply autogenous vaccines, and supply collecting outfits in which infectious material may be taken from the patient and mailed to the laboratory for isolation and growth of the organism and the preparation of the autogenous vaccine. (1, 2, 52.)

TUBERCULINS

Tuberculins are extracts or suspensions of the tubercle bacillus substances. A large number of preparations have been advanced from time to time, for each of which, special advantages or properties have been claimed. Only those

which have been accepted and described in New and Non-official Remedies will be mentioned here. These are often designated by symbols, as follows: "O.T."—Koch's Old Tuberculin; "T.R."—Tuberculin Residue, Tuberculin Rückstand, Koch's New Tuberculin; "B.E."—Bacillen Emulsion; "B.F."—Tuberculin Denys or Bouillon Filtrate.

Preparation—*Tuberculin O.T.* is essentially a glycerin bouillon extract of tubercle bacilli. The culture is grown in glycerin bouillon and this is sterilized by heating with steam, and reduced by evaporation to one-tenth the original volume. The bacilli themselves are removed by filtration. The filtrate is a brownish colored liquid and keeps indefinitely.

Tuberculin T.R. or *Tuberculin Residue* is made from living dried tubercle bacilli which are thoroughly ground and extracted in water. By centrifuge, extractives contained in the supernatant fluid are separated. The sediment is reground, extracted, and centrifuged as before, the process being repeated until practically no sediment remains. Fluid portions are combined and diluted with glycerin until the solution contains the residue of 10 mg. of dried tubercle bacilli per cc. It is a colorless liquid.

Tuberculin B.E. or *Bacillen Emulsion* is a suspension of dried, pulverized tubercle bacilli in equal parts of water and glycerin. Sediment is removed and the emulsion standardized to represent 5 mg. of tubercle bacilli per cc.

Tuberculin B.F., Bouillon Filtrate, or *Tuberculin Denys,* is a culture of tubercle bacilli from which the bacilli are removed by filtration. It contains all the soluble products of the growth of the *tubercle bacillus,* but differs from Tuberculin O.T. in that no heat is applied during the course of preparation.

Action and Uses—The tuberculins are not toxins, like the Diphtheria Toxin or Scarlet Fever Streptococcus Toxin. This is proved by the fact that relatively large amounts may be injected into a healthy non-tuberculous subject, without any ill effect. On the other hand very small amounts will produce a reaction in tuberculous subjects. Tuberculins have little or no antigenic power and are of negligible immunizing value. Nevertheless, they have, in the opinion of those who have used them, a definite place in the treatment of selected cases of tuberculosis, especially in those of a chronic and localized character. The benefit derived from their use must be ascribed to the tuberculin reaction.

FIG. 796

Growing tubercle bacilli in mass cultures for the production of Tuberculins. The tubercle bacilli appear as spongy white growth on the surface of the medium in the bottles.

So small an amount as 0.00,000,01 of a cc. of tuberculin may cause symptoms of illness in a tuberculous subject. The tuberculin reaction is accompanied by local reactions and also a focal reaction, that is, a reaction at the site of the lesions. The local reaction is employed as a means of diagnosis.

Recovery from tuberculosis is commonly regarded as resulting from the formation of fibrous tissue around the foci of infection, or tubercles, thus forming a dense capsule within which the tubercle bacilli are imprisoned. There is some evidence that the administration of tuberculins in suitable dosage sets up a slight inflammation and chronic local congestion at the site of the lesions, and that this congestion favors the formation of fibrous tissue, thus promoting the walling-off of the lesion. Tuberculin therapy is therefore considered most promising in chronic tuberculosis with localized lesions. The use of tuberculins in treatment requires special knowledge and experience, the great danger being in the administration of too large doses. Doses that are

too large produce severe reactions with ill effects on the patient. Physicians applying tuberculin therapy realize that the susceptibility to tuberculins in different patients varies considerably, and they take every precaution not to exceed the patient's tolerance.

The diagnostic uses of tuberculins are discussed in Chapter CXXII.

Dose—In treatment, an initial dose may consist of 0.00,000,001 to 0.00,000,1 cc. Not more than two doses per week should be given. No fixed dosage schedule can be given because different patients vary greatly in their sensitiveness to tuberculin. Subsequent doses are gradually increased but always keeping them low enough to prevent any marked constitutional disturbances. Tuberculin therapy should be accompanied by the usual measures of rest, diet and proper hygiene.

Different kinds of tuberculins vary in strength and even different lots of the same tuberculin may vary somewhat. It is a wise precaution, therefore, during a course of treatment, when a package of tuberculin bearing a new laboratory number is first used, to reduce the dosage one-half, in order to guard against possible change in strength.

Dosage Forms Available—*Tuberculin O.T.* Marketed in 0.5 cc., 1 cc., and 3 cc. vials, and in various serial dilutions.
Manufacturers—1, 2, 8, 14, 17, 56, 63.

TUBERCULIN T.R.—Marketed in 1 cc. vials and in serial dilutions.
Manufacturers—1, 2, 56.

TUBERCULIN T.R. DRIED—In vials containing ten tablets, five concentrations, (1) 0.0001 mg., (2) 0.001 mg., (3) 0.01 mg., (4) 0.1 mg., and (5) 1 mg. Tuberculin T.R. per tablet.
Manufacturer—1.

TUBERCULIN B.E.—Marketed in 1 cc. and 3 cc. vials, and in serial dilutions.
Manufacturers—1, 2, 17, 63.

TUBERCULIN B.E. DRIED—In vials containing ten tablets, five concentrations, (1) 0.0001 mg., (2) 0.001 mg., (3) 0.01 mg., (4) 0.1 mg., and (5) 1 mg. Tuberculin B.E. per tablet.
Manufacturer—1.

TUBERCULIN B.F.—Marketed in 1 cc. and 3 cc. vials, and in serial dilutions.
Manufacturers—1, 2, 8, 17, 56, 63.

CHAPTER CXXI

PROTEINS AND PROTEIN THERAPY

PROTEINS, ATOPENS, ALLERGENS, AND ANTIGENS

In Chapter CXVIII, some of the manifestations of protein sensitization were briefly discussed. Mention was made of the widespread occurrence of hay fever, of the relation of various proteins to asthma, and of a few facts concerning serum sickness. But there are many other manifestations of protein sensitization with which the physician has to familiarize himself, as cases of this sort are met with every day. One authority has stated that protein sensitiveness is a type of illness which affects, in slight or marked degree, about fifteen per cent of individuals. It is not only a common cause of annoying minor conditions but a rather frequent cause of severe illness.

Protein sensitization is a condition of hypersensitiveness to foreign proteins. A certain percentage of individuals inherit a constitution which easily becomes sensitive, and once sensitive, severe symptoms may appear whenever the patient comes into intimate contact with the foreign protein in question. This condition of sensitiveness has been given various names. Frequently the name "*allergy*" is applied, which conveys the idea of an altered or change reaction to the presence of foreign proteins. Another term proposed is the word "*atopy*", literally meaning a strange disease. It is used, like "*allergy*", to cover a broad group of illnesses due to proteins. Similarly, the agents which cause this type of illness, and the remedies which are used in their treatment, have been given different names, including "*allergic proteins*", "*allergens*", "*atopens*", and "*antigens*". For practical purposes the pharmacist can regard these terms as synonymous.

The Products Which Cause Hypersensitiveness—The allergic or atopic agents responsible for the many symptoms of protein sensitization comprise a very extensive list, and include almost every protein-containing substance which is ingested with food, inhaled in the air or which comes in contact with the body surface. Patients may exhibit sensitiveness to pollens or plants, emanations from animal hair or feathers, to dust, smoke, inhaled with the air, and to animal and vegetable foods and to other substances, such as bacterial proteins, insects, etc. Duke has recently pointed out that some human beings are also apparently sensitized by non-antigenic substances and may exhibit symptoms even by contact with inorganic matter or in response to a physical agent, such as light, cold, etc.[1] Duke has well stated that "relatively little is positively known concerning the physical or chemical make-up which characterizes agents which can sensitize human beings. More is known concerning their location.

"It is not difficult in many cases to trace the source of an illness to contact with substances, such as milk, egg, pollen, animal hair, feathers, cottonseed, orris, or flax, or to constituents of these which can be extracted with salt solution or glycerin, or even to relatively well purified constituents, such as ovomucoid, egg-white, or lactalbumin. It is very difficult, however, to identify and place the blame on the chemical body actually responsible. It is difficult even to classify it as protein or non-protein, organic or inorganic. The mere fact that an individual reacts to a certain protein cannot be looked upon as

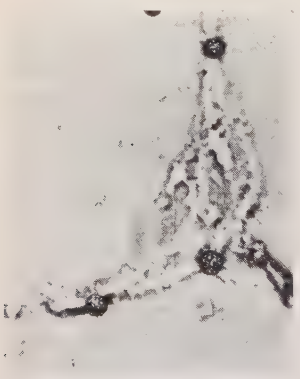
[1] Duke, W. W., Asthma, Hay Fever, Urticaria, 1925

conclusive evidence that the suspected protein is actually the cause of reaction for it is perfectly possible that the offending agent simply accompanies certain proteins, just as diphtheria antitoxin accompanies certain globulins of the serum."

Present knowledge does, however, warrant the definite statement that, in sensitive individuals, "*atopens*" or the substances which produce sensitization, may act as violent poisons in almost infinitesimal doses. Even so small a dose as 1/10 cc. of a 1 in 10,000 solution of a pollen may cause a severe reaction in a sensitive hay fever subject. Another observation based on clinical experience is the fact that some substances sensitize patients more easily than others.

The Symptoms of Specific Hypersensitiveness—Protein sensitization is a common cause of illness, of which the symptoms and manifestations are varied. In fact, almost any tissue or organ in the body may be involved. The more common symptoms are those which involve the mucous surfaces, especially the membranes of the nose, throat, bronchial tubes, the conjunctiva, and the membranes lining the gastro-intestinal tract. Symptoms involving the skin and subcutaneous tissues are less common, and are usually a part of a general reaction following the absorption of an offending protein.

FIG. 797



Showing ragweed pollen grains in nasal secretion from hay fever patient. After Scheppegrell.

The more important symptoms have been conveniently summarized as follows[2]:

1. Nasal—Sneezing, pallor and swelling of mucous membrane, usually with excessive watery or clear mucous secretions (see Fig. 797).
2. Pharyngeal—Itching of the soft palate and pharynx, spasmodic cough.
3. Bronchial—Bronchial obstruction with inspiratory and expiratory wheezing, and often with the expectoration of clear mucoid sputum. In milder cases cough and shortness of breath on exertion.
4. Ocular—Edema of the conjunctiva, puffiness, itching, swelling and redness of the lids. Excessive lacrimal secretions.
5. Cutaneous—Urticaria (an itching eruption), angioneurotic edema (swelling due to injury to the nerves which control the circulation), eczema, erythema, and pruritis, either local or general.
6. Gastro-intestinal—Abdominal pain (either steady or griping, local or general; mild or severe), nausea, vomiting, bloating, diarrhea, mucous colitis, etc.
7. Neurological—Asthenia (weakness), and a sensation described as nervousness.
8. Arthritis—Joint pain and swelling is a very definite and interesting manifestation of allergy.
9. Blood Pressure—Often reduced to from 90 to 110 mm.
10. Headache.
11. Bladder—Frequent painful micturition.

Diagnosis and Treatment—The diagnosis of protein sensitization is made, in the majority of cases, through the information gained by the history, by physical examination, and from cutaneous or clinical tests. The cutaneous

[2] From Duke, Ann. of Clin. Med., Vol. I, Nov., 1922

tests are usually indispensable. A brief description of the cutaneous tests and a discussion of the products used therein will be found in the next chapter.

Treatment of these conditions may be approached in four ways: (1) by the removal of the cause, (2) by specific protein treatment, (3) by non-specific protein treatment, and (4) by symptomatic treatment. Removal of the cause is the simpler method in many instances. Where this cannot be effected, specific protein treatment is the method of choice. Treatment consists in giving subcutaneously a series of injections with an extract of the offending protein. Infinitesimal doses are given first, which are then increased as rapidly as the patient's tolerance will permit, and is continued until the patient acquires enough resistance or tolerance to withstand the amount with which his habits and environment bring him into contact. Clinical investigation with different methods of specific protein treatment have gradually led to an appreciation of what Duke calls the "short interval method". This method, as applied in the treatment of hay fever, consists of an infinitesimal initial dose, subsequent doses being given twice a day or more usually once a day during the first part of the treatment, the dose being doubled at each inoculation, or as rapidly as the tolerance of the patient will permit. As the higher doses are reached, it is frequently necessary to space out the time intervals to two or even three day intervals. The time intervals and the rate of increase in dosage will vary, and are adjusted to suit the case. The immunity or tolerance developed is often of short duration. In hay fever, for example, it persists little more than six or eight weeks. It is not necessary to discuss here any of the special points in the technic of treatment, enough having been said to explain the nature and the contents of many of the packages of protein substances which the pharmacist is called upon to distribute.

Dose—It is regarded important to start with a dose which will not cause an intense local reaction. The initial dose, therefore, is chosen very carefully and is usually based upon the information gained from the cutaneous tests. If the skin reaction has been a vigorous one, indicating a high degree of sensitivity, then the initial treatment dose must be correspondingly small, little larger than the test dose, in fact. The commercial houses supply protein extracts in dilutions which lend themselves to a suitable scale of dosage for average cases. Some of the products are labeled to show their strength in terms of the degree of dilution, others by chemical analysis of the protein content.

Simple Protein Preparations

POLLEN EXTRACTS, POLLEN ATOPENS, POLLEN ALLERGENS, AND POLLEN ANTIGENS

Liquids obtained by extracting the dried pollen of plants and used for the diagnosis, prophylaxis or relief of hay fever or pollinosis.

Preparation—There are several methods of extraction in common use. Most of them involve a preliminary grinding of the dried pollen in order to break the cell membranes. The subsequent procedures include the following:

(a) Extraction with water containing phenol 0.5 per cent. The resulting extract is standardized by determining the protein content. (2)[1]

(b) Extraction is done with 1 per cent sodium chloride solution and the extract is diluted with glycerin and 1 per cent sodium chloride solution until the final volume contains 60 per cent glycerin. (52)

(c) Extraction is done with physiological sodium chloride, and alcohol added to make 12 per cent. After twenty-four hours, the mixture is centrifuged and the supernatant fluid drawn off. The resulting extract is a 12 per cent alcoholic solution. From this, sterile dilutions are prepared for administration. (67)

[1] Numbers in parenthesis are license numbers of manufacturers.

(d) Extraction is done with sodium chloride, followed by clarification by filtration, and standardized on the basis of the amount of pollen extracted. (1)

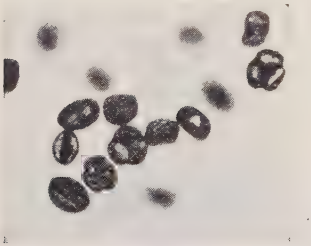
(e) Extraction is done in a solution containing 67 per cent glycerin and 33 per cent saturated sodium chloride solution, and the total volume adjusted so that 1 cc. is equivalent to about 14,000 pollen units, the pollen unit having been arbitrarily chosen as the equivalent of 0.001 mg. of pollen. The solution is standardized by complement fixation tests. (17)

(f) Extraction is done in glycerin-sodium chloride solution, and sufficient of the solution is added so that each cc. represents about 10,000 pollen units. (58)

In all the methods the final steps involve the sterilization of the pollen extracts by filtration and filling them into sterile market containers. Tests for sterility are made after dilution and after filling.

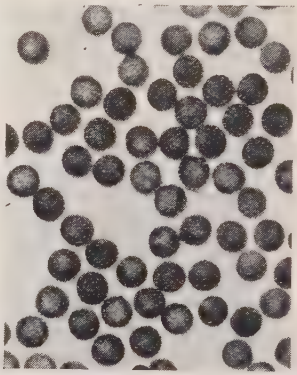
A pollen extract prepared from the pollen of one plant is not intended for use in hay fever caused by the pollen from other plants. Yet hay fever sufferers are frequently sensi-

Fig. 798



Pollen grains of the Absinth Wormwood (greatly magnified). A primary cause of fall hay fever in certain parts of the country. After Scheppegrell.

Fig. 799



Pollen grains of the Marsh Elder, *Iva ciliata* (greatly magnified). One of the causes of hay fever. After Scheppegrell.

tive to more than one pollen, and very often these are closely related botanically. Some authorities have held the opinion that the extract of a given pollen will produce a certain amount of tolerance, on the part of the patient, to pollens of botanically related plants. For example, Timothy extract is said to give some protection against pollens of closely related grasses. Following is a list of pollen extracts arranged alphabetically by the English common name of the plants. Certain ones among them are the principal factors of hay fever and therefore the extracts are the ones most often called for. Timothy, Orchard Grass, and June Grass are by far the most important of the grasses and are responsible for hay fever symptoms in the late spring and early summer. They have a very wide distribution. In certain sections of the country, Bermuda Grass and Johnson Grass are primary causes, as in the Southwest. In the fall the common ragweeds are responsible for perhaps 90 per cent of the hay fever cases in the eastern part of the United States, while the most important factors in the West are the various sagebrushes and wormwoods. Local importance of other pollens has been brought out in the literature from time to time. Russian Thistle, for example, has been identified as a primary cause in the State of Washington, and Mountain Cedar, in portions of Texas.

A List of Hay Fever Pollen Extracts Supplied for the Prophylaxis and Treatment of Hay Fever

Annual Salt Bush	Birch	Cedar
Amaranth, Spiny	Box Elder	Cherry
Arizona Cottonwood	Brome Grass	Clover
Ash, Arizona	Burr Ragweed	Cocklebur
Ash, White	Burroweed	Corn
Aster	Canary Grass	Cottonwood
Bermuda Grass	Careless Weed	Dahlia

List of Hay Fever Pollen Extracts—*Continued*

Daisy	Orchard Grass	Sage, Hill
Dandelion	Perennial Rye	Sage, Pasture
Dock	Pine	Sage, Prairie
Elm	Plantain	Sagebrush
Goldenglow	Poplar	Saltbush
Goldenrod	Poppy	Sandbur
Greasewood	Quailbush	Sea Blite
Hemp	Rabbitt Bush	Shadscale
Hickory	Ragweed, False	Sorrel
Johnson Grass	Ragweed, High	Sudan Grass
June Grass (Blue Grass)	Ragweed, Low	Sugar Beet
Locust	Ragweed, Prairie	Summer Cypress
Maple	Ragweed, Slender	Sunflower
Marsh Elder	Ragweed, Southwestern	Sweet Vernal Grass
Mexican Tea	Ragweed, Western	Sycamore
Mountain Cedar	Red Top	Walnut, Arizona
Mugwort	Redroot Pigweed	Walnut, Black
Mulberry, Black	Rose	Walnut, California
Narcissus	Russian Thistle	Water Hemp
Nettle	Rye	Wild Sunflower
Oak, White	Sage, Carpet	Willow
Olive	Sage, Green	Yellow Dock

Dosage Forms Available—Extracts of a few of the more important pollens are supplied in 10, 15, and 20 dose treatment sets. The doses are graded and are intended to offer a convenient series suitable for the prophylaxis of cases of average sensitivity. Also supplied in vials of graduated concentrations, namely, 1 in 10,000, 1 in 5000, 1 in 1000, 1 in 500, and 1 in 100. Practically all are supplied in 5 cc. vials, in concentrations which lend themselves to such gradations of dosage as the physician may find it advisable to adopt.

Manufacturers—1, 2, 17, 43, 51, 52, 58, 67.

FOOD EXTRACTS, FOOD ATOPENS, FOOD ALLERGENS, AND FOOD ANTIGENS

Extracts of food substances are used in the diagnosis and desensitizing treatment in cases in which persons show a peculiar hypersensitiveness towards certain articles of the dietary. Their purpose is twofold: to identify the food which produces the untoward symptoms and, to a lesser extent, by their proper application to raise the tolerance of the patient. If the offending food cannot be eliminated entirely from the diet, specific desensitizing treatment is instituted.

Preparation—Several different methods of preparation are necessarily employed because of the wide differences in the composition and properties of the food substances concerned. Those interested in this phase of the subject will find a condensed review in the N. N. R.

List of Some of the Food Protein Extracts Offered by Biological Houses

Few, if any, of these preparations are stocked by druggists and the manufacturers usually make them up only on order.

Almond	Casein	Lamb
Apple	Cauliflower	Lettuce
Apricot	Celery	Lobster
Asparagus	Cheese	Mackerel
Banana	Chicken	Milk
Barley	Clam	Mushrooms
Bean, Lima	Cocoa	Oat
Bean, Navy	Corn	Onion
Bean, String	Coffee	Orange
Beef	Codfish	Oyster
Beet	Cucumber	Pea
Buckwheat	Eggplant	Peach
Cabbage	Egg Yolk	Peanut
Cantaloupe	Egg White	Pear
Carrot	Grapefruit	Pecan

List of Some of the Food Protein Extracts—*Continued*

Pepper, Black	Rye	Tea
Plum	Salmon	Tomato
Pork	Squash	Turnip
Potato	Spinach	Veal
Prune	Strawberry	Walnut, English
Rice	Sweet Potato	Wheat

Dosage Forms Available—Commonly supplied in 5 cc. vials, in concentrations which lend themselves to suitable gradation of dosage.

Manufacturers—1, 2, 17, 52, 58, 67.

ANIMAL EXTRACTS, ANIMAL ATOPENS, ANIMAL ALLERGENS, AND ANIMAL ANTIGENS

These products are extracts of animal hair and feathers and are used in the prophylaxis and relief of cases of asthma, perennial rhinitis, or other manifestations of sensitiveness to these substances. They are sometimes spoken of as epidermal extracts. They constitute an important cause of reactions, although by no means as numerous as cases of pollen sensitiveness. Frequent exposure is a factor in the development of sensitiveness. One whose occupation brings him in frequent contact with a given animal is more likely to become sensitive to it than to others encountered but rarely. Sensitiveness to animal atopens may be either slight or intense. In the mild cases, sneezing and itching of the eyes may be the only symptoms. In severe cases serious reactions, which may amount to shock, may occur on slight contact. Hair and feathers, being used extensively in the manufacture of wearing apparel, upholstery, rugs, bedding, etc., are frequently responsible for the so-called "house asthma".

Preparation—Various methods of preparation are employed. In most instances the finely divided hair, feathers, or dander are extracted with 0.2 per cent sodium hydroxide solution. The protein is then precipitated. The precipitate is redissolved and standardized by chemical determination of protein nitrogen.

List of Animal Extracts—Following is a composite list of animal extracts offered by biological houses. Few, if any, of these preparations are stocked by druggists and some of the less frequently used are made up by the manufacturers only on order.

Burro Hair	Cow Dander (Cattle Dander)	Horse Hair
Burro Dander	Dog Hair	Horse Serum
Cat Hair	Dog Dander	Human Hair
Cat Dander	Duck Feathers	Human Dander
Chamois Skin	Goose Feathers	Rabbit Hair
Chicken Feathers	Guinea Pig Hair	Rabbit Dander
Cow Hair	Horse Dander	Sheep's Wool

Pollen grains of the Black Walnut, *Juglans Nigra* (greatly magnified). A cause of some cases of hay fever of the early spring type.

Dosage Forms Available—Commonly supplied in 5 cc. vials.

Manufacturers—1, 2, 17, 52, 58, 67.

MISCELLANEOUS PROTEIN EXTRACTS, MISCELLANEOUS ATOPENS, MISCELLANEOUS ALLERGENS, AND MISCELLANEOUS ANTIGENS

Certain substances which do not fall in the above groups, are sometimes factors in asthma or other manifestations of protein sensitization. There is ample evidence, for example, that some individuals are sensitive to dust, and in fact, to dusts of certain types. It has been shown that a patient may be sensitive to the dust of certain houses but not to the dust of others. Some patients react to mill dust or stable dust and other specific forms. Another rather frequent cause of illness is traced to orris root, and rice powder is likewise frequently incriminated.

Preparation—Methods of preparation vary with each item of the list. The reader is referred to the N. N. R. for a brief review of the principal methods of extraction used.

List of Miscellaneous Extracts —The following is a composite list of miscellaneous protein extracts supplied by biological houses.

Cottonseed	Kapok	Silk
Flaxseed	Orris Root	Tobacco
Glue	Rice Powder	Yeast
Hay		

Dosage Forms Available—Commonly supplied in 5 cc. vials.
Manufacturers—1, 2, 17, 52, 58.

BACTERIAL PROTEIN EXTRACTS, BACTERIAL ATOPENS, BACTERIAL ALLERGENS, AND BACTERIAL ANTIGENS

Bacteria or bacterial products may occasionally be responsible for symptoms of protein sensitization similar to those caused by pollens and the like. Nasal reactions or asthmatic breathing may be the result of an acute or chronic infection in the nose, nasal sinuses or bronchial tubes. The diagnosis of bacterial allergy or atopy is difficult and reactions which can be conclusively attributed to bacterial proteins are rare. When such conditions are found the treatment involves removal of the focus of infection, if possible, and the use of bacterial vaccines of the usual kind in desensitizing treatment.

Manufacturers—For the source of supply, see the manufacturers of bacterial vaccines, page 1936.

CHAPTER CXXII

BIOLOGICAL PRODUCTS USED AS DIAGNOSTIC AGENTS

Of the numerous biological products used in the diagnosis of disease, the pharmacist is called upon to handle and distribute chiefly the proteins (atopens, allergens, including hay fever pollens), the toxins and tuberculins. Other diagnostic reagents either do not have the requisite keeping qualities and therefore have to be made up fresh just before use, or their employment is limited to a few clinical or pathological laboratories. The proteins, toxins and tuberculins, on the other hand, lend themselves to practical use in the hands of the general practitioner even in communities remote from modern hospital and laboratory facilities.

The technic of using these products in testing is simple and easily carried out. The products themselves possess good keeping qualities. A brief description of the methods of making the tests is given here to explain how they are used. It should be added, however, that physicians do not depend upon these tests exclusively in arriving at a diagnosis, but depend to an equal, if not greater, degree upon clinical observations and the case history.

SKIN TEST METHODS

The Cutaneous or Scratch Test—This test is done by first cleansing the skin on the inner surface of the forearm with alcohol. When this has dried, abrasions or short scratches are made, one for each substance to be tested, and one or two extra for controls. In most cases a series of linear scratches, each about one-eighth of an inch long, and never more than one-fourth of an inch, are placed at least two inches apart. Care is exercised to see that these scratches penetrate only the outer layer of the skin and are not deep enough to draw blood. The scratches or abrasions may be made with a needle, as commonly done in vaccinating for smallpox, or with the point of a sharp scalpel, or with a Von Pirquet skin borer. Ten or more tests may be conducted at one time. A small droplet of tenth-normal sodium hydrate solution is applied to each scratch or abrasion. Then the foreign materials to be tested are applied in dried powdered form, one to each of the scarified areas. Sufficient of the powder in question is conveniently taken up on the end of a tooth-pick and applied by rubbing it gently into the scratch or abrasion. The control scratches receive the tenth-normal sodium hydrate only. Normal salt solution may be used instead of the sodium hydrate.

Fig. 801

Showing skin tests with hay fever pollens. Of 16 pollens applied, 5 gave positive reactions; 4 on patient's right arm and 1 on the left. Note characteristic wheals or hives, with "pseudopods". Photo by Dr. Holliger, Fresno, California.

Twenty minutes or one-half hour later the proteins are washed off and the results interpreted and recorded. Reactions, if any, will have reached their height by that time. A typical positive reaction consists of an urticarial wheal or hive, surrounded by an area of redness (erythema). The recent tendency is to attach greatest importance to those reactions which exhibit

a wheal with irregular margins (pseudopods). "Button reactions" (a wheal without pseudopods) or an erythema only, is regarded as negative or indicating only a partial degree of sensitization. A positive reaction, of course, must be read in comparison with the controls and must be definitely larger and more clearly defined. Usually the control test will show only a small area of slight redness around the site of the scratch, but in some individuals sensitive to sodium hydrate, considerable reaction may appear which may necessitate repeating the test with a different diluent, salt solution, for example, before the correct diagnosis of the protein sensitiveness can be arrived at.

The cutaneous or scratch method is easily performed, is fairly accurate, and has the advantage that if the patient shows extraordinary sensitiveness to the protein, excess protein can be washed off and thus absorption stopped before any severe effects are likely to develop. In making this test the physician may use proteins or pollens in dried powdered form, or pollens and proteins in paste or ointment form. Liquid preparations of proteins may also be used in the proper concentration, by applying a small droplet of the extract to the abrasion or scratch. In such case no other liquid is applied, sodium hydrate and salt solution being omitted as unnecessary and interfering with the direct action of the extract to be tested. As a general rule, reactions to proteins begin to fade after half an hour, but will continue in evidence for two or three hours.

The Intracutaneous or Intradermal Test—Standardized solutions of the diagnostic reagents, whether protein extracts or toxins or tuberculin solution, may be injected intracutaneously, that is, between the layers of the skin on the inner surface of the forearm, previously cleansed in the usual manner. A small syringe graduated in 10ths or 20ths of a cc. is used, with a 26 or 27 gauge needle. The test is made by holding the needle first at an angle of 45 degrees, with the bevel side up, and inserting it just far enough to engage the point. The syringe is then lowered so that the needle point will travel parallel to and between the layers of the skin. It is advanced until all the beveled portion of the needle is between the layers of the skin. The point of the needle and the opening can be seen through the thin membrane of the epidermis covering it. A tiny droplet of the solution, usually 1/20 (0.05) cc., or 1/10 (0.1) cc., is injected. This forms a tiny blister-like elevation at first. In allergic tests, results are read twenty to thirty minutes later. Typical reactions, corresponding to those observed with the skin or cutaneous test, consist of a wheal or hive with pseudopods and erythema. With the toxins and tuberculins the results do not appear as early as this and the appearances are different. These reactions are discussed on a later page.

The intradermal test is also comparatively simple and presents no particular difficulties to the practitioner. As Duke has stated, the difficulty in technic does not lie in the injection, but in the preparation of the solutions for testing. It is only natural, therefore, that preparation of the solutions should be generally left to the laboratory experts, and their general distribution to the pharmacist.

PROTEINS, ATOPENS, ALLERGENS OR ANTIGENS USED IN DIAGNOSIS

Practically all the pollen, food proteins, animal proteins, epidermal proteins, bacterial proteins and miscellaneous items, which have already been listed in Chapter CXXI, pages 1928 to 1930, are available in dried powdered form suitable for, and intended for, use by the cutaneous or scratch method.

Most of the items in these lists are also put up in paste form, in collapsible tubes. Paste is applied to the scratch or abrasion and rubbed in gently after the same manner as the

powder is used. The paste is washed off after twenty or thirty minutes and reactions interpreted as described above.

A number of items other than those mentioned in the lists above referred to are often available. Without repeating these lists, it will be sufficiently useful to give information here on the packages available.

Dosage Forms Available—Pollens and proteins, in the form of dried powder, are available in 25 mg. vials, containing sufficient material for ten or twelve tests, and in 50 mg. vials, containing sufficient material for twenty-five tests; also in capillary tubes containing enough material for one test. These are supplied singly or in packages of six.

Manufacturers—2, 52, 67.

Pollens and proteins, in paste form, for diagnostic use are supplied in collapsible tubes containing 1.5 Gm. of the paste, or sufficient material for about 50 tests.

Manufacturer—1.

PROTEIN MIXTURES FOR DIAGNOSIS

Group Tests—Mixtures of closely related proteins are made available for testing, with the idea that preliminary group tests will help to reduce the total number of skin tests required to reach a specific diagnosis, because they may often indicate whether the patient's sensitiveness is in a certain class, like sea foods, grains, animal epidermal products, or the like. If sensitiveness to a given group is indicated by a positive reaction, then further tests with the individual members of the group will serve to identify the inciting agent. These protein mixtures include most of the common food, animal and bacterial proteins, and are arranged in some 27 groups, each containing from three to six more or less related substances.

FIG. 802

Series of cutaneous tests on leg of hay fever patient, showing three strongly positive reactions; to June Grass, Sweet Vernal Grass and Timothy. Photo by Dr. Holliger, Fresno, California.

Dosage Forms Available—Supplied in powdered form for diagnostic use by the cutaneous or scratch tests, in vials containing 25 mg.

Manufacturer—52.

Supplied in paste form in collapsible tubes containing approximately 1.5 Gm. of a paste containing mixed proteins sufficient for fifty tests.

Manufacturer—1.

TOXINS USED IN DIAGNOSIS

The Diphtheria Immunity Test or Schick Test—This test is the means by which those who are susceptible to diphtheria may be detected. It consists essentially of an injection between the layers of the skin of a very minute amount of diluted diphtheria toxin, and its diagnostic value depends upon the fact that a person who has no free antitoxin in his blood will develop a circumscribed area of redness and infiltration of from one to two centimeters in diameter around the site of the injection. Should the patient have free antitoxin in his blood no reaction occurs. In non-immune persons the reaction appears in twenty-four to forty-eight hours, is at its height from forty-eight to seventy-two hours, and then gradually disappears, so that after seven to fourteen days only a brownish pigmentation and surface scaling remain to indicate the site of the test.

Preparation—Schick Test Toxin is a diphtheria bacillus toxin, filtered and carefully tested and standardized. Both potency and clinical tests are carried out and the product is adjusted to a strength such that the amount commonly used in the ordinary Schick Test represents only 1/50 of the fatal dose for a 250 gram guinea pig. This conveys some idea of the safety of the toxin, when diluted for use in testing human beings. It means that it would require fifty human doses to cause the death of a medium sized guinea pig.

Diphtheria Toxin for the Schick Test does not keep well in diluted form. The dilution must be freshly prepared just before use. The product is therefore usually supplied in packages of two containers, in one of which will be found the Diphtheria Toxin and in the other, sterile sodium chloride for use as the diluent.

Uses—The Schick Test is of value in institutions, schools, and in groups of persons exposed to diphtheria, for the purpose of determining who are susceptible and thereby indicating those who should be given a temporary immunizing dose of Diphtheria Antitoxin, or the active-immunity stimulant—Toxin-Antitoxin Mixture (see page 1916).

Dosage Forms Available—Packages ordinarily supplied consist of two containers, one, a vial or capillary tube containing a definite volume of Diphtheria Toxin, the other con-

taining sterile physiological solution of sodium chloride, with which the toxin is to be diluted before administration. They are to be had in packages containing sufficient for 10, 20, 50 and 100 tests. Some are supplied in dilutions so that 2/10 (0.2) cc. of the dilution is the correct intradermal dose. Others are supplied in dilutions of which 1/10 (0.1) cc. represents the proper intradermal dose.

Diphtheria Toxin Control for the Schick Test is also available. This represents Diphtheria Toxin heated sufficiently to destroy the specific exotoxins. This material is supplied already diluted, for use in doses of the same size as the toxin in the Schick Test.

Manufacturers—1, 2, 8, 14, 17, 52, 56, 63, 64, 65.

Scarlet Fever Immunity Test or Dick Test—Approved products, under license from the Scarlet Fever Committee, Inc., are supplied under the name Scarlet Fever Streptococcus Toxin for the Dick Test. It is a soluble toxin derived from the hemolytic streptococci of scarlet fever. Intradermal injections of this toxin, properly diluted, give positive skin reactions in susceptible persons, but no reaction in those immune to scarlet fever. The nature of the reaction is quite similar to that produced by Diphtheria Toxin in the Schick Test, except that it produces somewhat less inflammation of the skin and the reactions are more transient. An area of redness is the principal characteristic of a positive reaction, and the rule is to regard any reddening of the skin, however faint, measuring over 1 cm. in diameter, as a positive reaction. The reaction reaches its height in from eighteen to twenty-four hours, and the reaction is read and recorded within that period.

Preparation—Scarlet Fever Streptococcus Toxin for the Dick Test is prepared by the proper dilution of the toxin obtained from cultures of scarlet fever streptococci, and standardized so that 1/10 (0.1) cc. contains one skin test dose. Standardization is done by comparison with a toxin of known strength, distributed by the U. S. Public Health Service.

Dose—1/10 (0.1) cc., injected intradermally or intracutaneously.

Dosage Forms Available—Marketed in 1 cc. containers sufficient for ten tests, and in 10 cc. containers sufficient for 100 tests.

Manufacturers—2, 52.

TUBERCULINS USED IN DIAGNOSIS

It has already been noted, page 1923, that tuberculins are not toxic for normal nontuberculous individuals, and that no reactions follow their application to the skin or injection into or under the skin. Subjects of tuberculous infection, whether in the active or inactive stage, are, on the other hand, very susceptible to small amounts of tuberculin. This susceptibility manifests itself as a so-called tuberculin reaction. The reaction may appear (a) simply as a local reaction at the site of injection and may vary in intensity from a slight redness and tenderness to severe inflammation; or (b) a focal reaction may appear in the region of the tubercular lesions, or (c) there may be a general constitutional reaction, with fever, loss of appetite and rapid pulse. Tuberculins are used in diagnosis with the realization that a tuberculin reaction simply points to the presence of a tubercular infection, but does not necessarily mean that the individual is suffering from an active or progressive form. Individuals with an arrested or inactive lesion will give positive reaction but they will remain healthy without developing symptoms of the disease. The tuberculin test is therefore never solely depended upon in diagnosis, but is of value when interpreted in connection with other signs and symptoms.

The tuberculin test may be applied by various methods, of which the following are the best known. They are arranged in the order of their sensitiveness and the descriptions are taken from Kolmer's textbook on Infection, Immunity and Biologic Therapy, 3rd Edition.

The Intracutaneous Tuberculin Test (Mendel and Mantoux) consists in injecting into the superficial layers of the skin 1/20 (0.05) cc. of diluted Old Tuberculin. A positive reaction is denoted by infiltration and congestion (hyperemia) about the site of the injection.

The Subcutaneous Tuberculin Test consists in the subcutaneous injection of diluted Old Tuberculin. A positive reaction manifests itself in a constitutional disturbance accompanied by fever, a local reaction at the site of injection, and frequently a focal reaction at the site of the lesions.

The Cutaneous Tuberculin Test or Von Pirquet Test consists in the local application of Old Tuberculin to a superficial abrasion of the skin. A positive reaction is indicated by redness, swelling, and other inflammatory signs.

The Percutaneous Tuberculin Test (Moro and Doganoff) consists in the application of Tuberculin Ointment prepared by mixing equal parts of Old Tuberculin and anhydrous lanolin, and applying it to the skin over the upper portion of the abdomen. A positive reaction is indicated by the appearance of papules on the anointed skin.

The Conjunctival Tuberculin Test (Wolff-Eisner or Calmette Test) consists of local application to the conjunctiva of one eye of a drop of 1 per cent solution of Old Tuberculin or Purified Tuberculin. A positive reaction is indicated by congestion and lacrymation.

OLD TUBERCULIN O. T.

Dosage Forms Available—Marketed in 0.5 cc., 1 cc., 3 cc. vials, and in various serial dilutions.

Manufacturers—1, 2, 8, 14, 17, 56, 63. There are also available special diagnostic tuberculin packages, as follows:

TUBERCULIN INTRACUTANEOUS for the intracutaneous test of Mantoux. Supplied ready diluted in syringes adapted for intradermal injection, in single test, five test, and fifty test packages. Dose, 1/20 cc. containing 0.00,005 cc. Old Tuberculin. The bovine type of O. T. Tuberculin is similarly supplied for diagnostic use.

Manufacturer—2.

Also marketed in packages of two vials, one containing concentrated Tuberculin and one of diluent, to be thoroughly mixed and used in 0.1 cc. amounts intradermally. This dose contains 0.00,001 Gm. of Tuberculin.

Manufacturer—17.

TUBERCULIN FOR THE VON PIRQUET OR CUTANEOUS TEST—For use in this test O. T. Tuberculin, both human and bovine types, is supplied in capillary tubes. Contents of each tube sufficient for one test. Packages of three and ten capillary tubes.

Manufacturers—1, 2, 17.

TUBERCULIN OINTMENT for the Moro Reaction or Percutaneous Test—O. T. Tuberculin in ointment form, both human and bovine types, are available in one gram and two gram tubes and in capsules. One gram tubes contain sufficient for four tests. Contents of each capsule is intended for one test.

Manufacturers—1, 2, 8.

TUBERCULIN DISKS for the Conjunctival Test—Tablets designed for ophthalmic diagnosis of tuberculosis in man. One tablet dissolved in 5 minims or 1/3 cc. sterile distilled water gives a 1 per cent solution, the strength generally recommended for instillation. Dose, one drop. Supplied in tubes, ten disks or tablets per tube.

Manufacturer—1.

THE DETRE-DIFFERENTIAL TEST—As stated in the N. N. R., Detre claims to be able to determine whether a patient is infected with human or bovine tubercle bacilli, and whether the disease is active or latent, by carrying out a Von Pirquet test with Old Tuberculin, human bacilli filtrate and bovine bacilli filtrate at the same time and measuring the size of the respective papules produced. The theoretical basis of this test is not thoroughly established. Many regard it as of little practical value.

Materials for the test are supplied in packages of three tubes of 1 cc., one each of Tuberculin O.T., Tuberculin B. F. Human, and Tuberculin B. F. Bovine.

Manufacturer—8.

KEY TO MANUFACTURERS OF BIOLOGICAL PRODUCTS

Biological products distributed in the United States are prepared under license from the U. S. Public Health Service, in accordance with the act of Congress approved July 1, 1902, entitled "An act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." Licenses granted by the Public Health Service mean that inspections of the establishments concerned, and laboratory examination of samples of their products, are made regularly to insure observance of safe methods of manufacture, to ascertain freedom from contamination, to determine potency, etc., but do not imply an endorsement of the claims made by the manufacturers for their respective preparations.

Manufacturers of biological products licensed by the U. S. P. H. S. are here listed in the order of the number of the license which has been issued to them.

License No.	*Manufacturer*
1.	Parke, Davis & Co., Detroit, Mich.
2.	H. K. Mulford Company, Philadelphia, Pa.
6.	Slee Laboratories, Swiftwater, Pa.
8.	The Cutter Laboratory, Berkeley, Calif.
11.	Institut Pasteur de Paris, Paris, France.
14.	Bureau of Laboratories, Dept. of Health, New York City.
17.	Lederle Antitoxin Laboratories, Pearl River, N. Y.
24.	Farbwerke Hoechst, vorm. Meister Lucius und Bruning, Hoechst am Main, Germany.
30.	Dr. G. H. Sherman, East Jefferson Ave., Detroit, Mich

License No.	*Manufacturer*
43.	The Abbot Laboratories, 4735 E. Ravenswood Ave., Chicago, Ill.
45.	Beebe Laboratories, St. Paul, Minn.
49.	Dr. W. T. McDougall, 640 Minn. Ave., Kansas City, Kans.
50.	St. Louis Pasteur Institute, 3514 Lucas Ave., St. Louis, Mo.
51.	The Upjohn Co., Kalamazoo, Mich.
52.	E. R. Squibb & Sons' Research and Biological Laboratories, New Brunswick, N. J.
53.	Laboratory of Clinical Pathology, 1208 Wyandotte St., Kansas City, Mo.
54.	Dr. James McI. Phillips, 2057 N. High St., Columbus, O.
56.	Eli Lilly & Co., Indianapolis, Ind.
58.	Swan Myers Co., 219 N. Senate Ave., Indianapolis, Ind.
63.	Gilliland Laboratories, Marietta, Pa.
64.	Antitoxin and Vaccine Laboratory, Dept. of Public Health, Commonwealth of Mass., Jamaica Plain, Boston 30, Mass.
65.	United States Standard Products Co., Woodworth, Wis.
66.	D. L. Harris Laboratories, Metropolitan Bldg., St. Louis, Mo.
67.	The Arlington Chemical Co., Yonkers, N. Y.
73.	Connaught Antitoxin Laboratory, University of Toronto, Canada.
74.	Les Etablissements Poulenc Freres, 92 Rue Vieille-du-Temple, Paris, III, France.
79.	Persson's Laboratories, Mount Clemens, Mich.
84.	Terrell Laboratories, 311 State Bank Building, Fort Worth, Tex.
85.	Jensen-Salsbury Laboratories, Kansas City, Mo.
86.	Cook Laboratories, 536 Lake Shore Drive, Chicago, Ill.
87.	Instituto Sieroterapico Milanese, Milan, Italy.
89.	W. F. Straub Laboratories, 5514–5520 Norwood Park Ave., Chicago, Ill.

PART XV

TOXICOLOGY AND ANTIDOTES

CHAPTER CXXIII

THE pharmacist is often called on in emergency to treat cases of poisoning. As time is so momentous a factor in these cases, he is not only justified but morally obliged to trespass on what may be, technically, the physician's field. It should be remembered that the pharmacist's duty, or license, never extends beyond the emergency first treatment; to neglect to call a physician at once is not only to fail in responsibility to the patient but also to lay oneself open to suit for manslaughter. As the pharmacist is not concerned with the management of these cases after the first emergency is past, consideration here has been limited to what must be done immediately, and to those measures which the pharmacist may reasonably be expected to be able to perform.

Promptness of action is perhaps the most important of all virtues in treating cases of poisoning; in a very large proportion of instances the fate of the patient depends on what is done in the first fifteen minutes after the ingestion of the drug.

Emetics—In a very large number of forms of poisoning, the emptying of stomach is of more practical utility than the administration of the antidote. Emetics are *contraindicated* in poisoning by mineral acids, by caustic alkalies or by strychnine. The most thorough means of evacuating the stomach is by means of the stomach tube (or "pump"); this, however, requires a familiarity with its use; in the hands of the unskilled it is capable of very serious damage. Practically the pharmacist will rely on emetic drugs; the frequent recommendation to provoke vomiting by tickling the back of the throat is so likely to fail and the need of quickness so urgent that one should not waste the time trying it; if some one else is obtaining the emetic drug, or if none is at hand, tickling the throat—which can best be done with a feather—may be practiced temporarily.

Among the emetics, for general use first place should be given to ZINC SULPHATE. Twenty grains, in a couple of ounces of tepid water, may be given at a dose and if emesis has not occurred, repeated in five minutes. APOMORPHINE HYDROCHLORIDE is perhaps the most certain, and one of the quickest, of the emetics but requires to be given hypodermically; the dose should not exceed one-tenth of a grain. A useful emergency emetic is MUSTARD; it is very efficient and prompt but unpleasant; give half a tablespoonful stirred up in a wineglassful of water. A lukewarm solution of ordinary SALT, 2 tablespoonfuls to a glass of water, will sometimes provoke vomiting, especially if combined with the throat tickling. COPPER SULPHATE (5 grains) may also be used.

Antidotes—There is much misunderstanding and consequent misuse of antidotes. First, a distinction is to be made between antidotes and antagonists; an antidote, properly speaking, is a substance which chemically lessens or destroys the activity of a poison; agents which are used to combat the baneful effects of poisons should be called antagonists.

In a great many cases the action of the antidote is only to lessen, not to abolish, the toxic properties of the poison; for instance, the precipitate formed

by either tannic acid or iodine with the alkaloids is by no means inert; it is simply relatively insoluble and the antidote therefore delays absorption of the poison until the stomach and intestines can be emptied. In most instances one should not trust to the antidote alone, but should use it in connection with methods for evacuation of the alimentary canal.

Universal Antidote—The dream of the ancients of finding some drug or combination of drugs, which would counteract the injurious effects of all poisons is about as likely of realization as the hope of Ponce de Leon of finding the fount of perpetual youth. Nevertheless, there have been devised mixtures which have more or less antidotal effect to so many substances that the high-sounding title of universal antidote is not altogether ridiculous. The most important of these are powders which depend for their value on their adsorptive properties. There are some colloidal powders which have the property of mechanically, or at least without causing any alteration of chemical structure, removing certain dissolved substances from their solution. Among these should be mentioned in particular certain clays, as *fuller's earth* and Lloyd's reagent, and the charcoals, especially *animal charcoal.* Of these, charcoal, while not the most efficient, is usually the one most quickly obtainable and therefore to be recommended; it may be given in tablespoonful doses; it is not necessary to stop to measure it accurately, for it is quite incapable of harm, only be sure to give enough. Many writers recommend that with the charcoal be combined magnesium oxide. The latter will neutralize any acid, lessen the irritative effects of many heavy metals (as copper sulphate, alum, etc.), tend to delay the absorption of alkaloids, and perhaps have some effect against arsenic. In view of the frequency of arsenical poisoning it is commonly advised to add ferric hydroxide to the universal antidote, but unless the ingredients for its preparation be readily at hand time should not be wasted trying to make it. In a case of poisoning by an unknown agent, emetics stand first in importance but it may be well to follow them with a mixture containing about one tablespoonful of magnesia and two tablespoonfuls of charcoal.

Where several antidotes are named choose the one that can be obtained most quickly. *Do not mix antidotes* either in the patient's stomach or outside. Generally speaking they are more likely to neutralize each other rather than the poison. Tannic acid, iodine, and potassium permanganate are all antidotal to the alkaloids but are all mutually incompatible.

Acids, Mineral, including **Hydrochloric, Sulphuric, Nitric,** or **Phosphoric Acids**—*Do not give emetics* because the stomach may be so weakened by the caustic effect of the chemical that it will rupture during the vomiting. Give an alkali; the one which can be used most quickly is the best. Where there is opportunity for choice, preference should be given to the Milk of Magnesia (2 tablespoonfuls) or Magnesium Oxide (1 teaspoonful), because they do not liberate carbon dioxide gas which may distend and overstrain the weakened walls of the stomach; this danger is, however, generally overestimated and should not lead to the withholding of carbonates when other alkalies are not available. Calcium carbonate in the form of Chalk (2 teaspoonfuls), or Chalk Mixture (2 fluidounces), has more neutralizing effect for the same amount of CO_2 gas than Sodium Bicarbonate (dose, 1 tablespoonful). In the absence of other alkali, Soap, or well diluted solutions of the hydroxides, may be used. Lime Water is often recommended but it should be remembered that it requires about two quarts of lime water to neutralize the same amount of

acid as one ounce of milk of magnesia. WHITE OF EGG may be used if no alkali is available.

Acid, Oxalic, and the Oxalates (**Salt of Sorrel, Ink Eradicator,** etc.)—The best antidote is some form of lime: CALCIUM CHLORIDE (20 grains); CHALK (a teaspoonful); most tooth-powders contain chalk and may be used as an antidote. In the absence of lime, magnesia may be used as an antidote either in the form of MAGNESIUM SULPHATE (1 tablespoonful) or MILK of MAGNESIA (2 tablespoonfuls).

Aconite—A rapid and exceptionally dangerous poison. Give EMETICS—ZINC SULPHATE (20 grains) or ground MUSTARD (2 teaspoonfuls). LUGOL'S SOLUTION (Liq. Iodi Comp., dose, 20 drops) is probably the best chemical antidote, although none are of much value. *Keep the patient in a horizontal position*; do not allow him to sit up even to vomit, turn the head to one side when vomiting. Keep the patient warm.

Alkalies, including **Sodium Hydroxide** (**Caustic Soda**), **Potassium Hydroxide** (**Caustic Potash** or **Lye**), **Calcium Oxide** (**Quicklime**), and **Ammonia**—*Do not give emetics!* The chemical antidote is any dilute acid; the best is VINEGAR (1 or 2 tablespoonfuls), diluted with an equal amount of water. DILUTED HYDROCHLORIC ACID (official) may be used (one-half to 1 teaspoonful), well diluted, according to the amount of alkali which has been taken. LEMON JUICE or ORANGE JUICE (2 or 3 tablespoonfuls), diluted, are also useful. OLIVE OIL or any bland fixed OIL (2 or 3 tablespoonfuls) are of service, both because of neutralizing effect and soothing action.

Ammonia Water—See Alkalies.

Antimony or **Tartar Emetic**—Give TANNIC ACID (20 grains) or GLYCERITE OF TANNIN (1 teaspoonful). Other tannin-containing drugs, as FLUIDEXTRACT OF GERANIUM (2 teaspoonfuls), or TINCTURE OF KINO, or of GAMBIR (2 or 3 teaspoonfuls) may be substituted. *Keep the patient in a horizontal position.*

Arsenic or **Fowler's Solution**—("Rough on Rats" and some other rat poisons contain arsenic). EMETICS are the most important; ZINC SULPHATE (20 grains) or ground MUSTARD (2 teaspoonfuls). The best chemical antidote is the official arsenic antidote FERRI HYDROXIDUM CUM MAGNESII OXIDO (one-half a tumblerful). It may be extemporized by adding either a solution of SODIUM CARBONATE or MILK OF MAGNESIA, to TINCTURE OF FERRIC CHLORIDE, and straining the precipitate through cheesecloth. Give 1 or 2 tablespoonfuls of the precipitate. MILK OF MAGNESIA has some antidotal effect but is less valuable than the iron.

Atropine—See Belladonna.

Barium Sulphide, or other salt of barium—Give any soluble non-toxic SULPHATE, as EPSOM SALT or GLAUBER'S SALT (the dose should be at least equal to the quantity of barium salt; if this is unknown, give 3 tablespoonfuls); SULPHURIC ACID may be used in an emergency but is less valuable because the large quantity of acid may irritate the stomach (the dose of Aromatic Sulphuric Acid to be given should be about 1 tablespoonful, well diluted). Follow the antidote by an emetic such as ZINC SULPHATE (20 grains).

Belladonna, Atropine, Stramonium (**Jimson Weed**), **Hyoscyamus** and allied drugs—Give EMETICS—ZINC SULPHATE (20 grains) or MUSTARD (2 teaspoonfuls); best chemical antidote is LUGOL'S SOLUTION (10 minims); TANNIC ACID (20 grains) is less valuable; CHARCOAL (2 teaspoonfuls) is also of some value. Whatever antidote is given the stomach should be emptied,

as none of them forms entirely harmless compounds. Poisoning by the Solanaceous drugs although often very alarming is not usually fatal.

Bichloride of Mercury—See Mercury.

Cannabis—No antidote known. Give Emetics. Very rarely does this cause dangerous poisoning.

Calabar Bean—See Physostigma.

Cantharides—Give Emetics—Zinc Sulphate (20 grains) or Mustard (3 teaspoonfuls). There is no chemical antidote but Charcoal (2 teaspoonfuls) may be useful for its adsorbent effect. After emptying the stomach give Mucilage of Acacia to soothe the stomach; avoid anything fatty or oily.

Carbolic Acid—See Phenol.

Caustic Potash or Soda—See Potassium Hydroxide.

Carbon Monoxide is the poisonous factor in illuminating gas, automobile exhausts, and mine "choke-damp". The most important treatment is maintaining oxygenation of blood by Artificial Respiration; Oxygen inhalation is also useful.

Chloroform—If taken by mouth give Emetic. Practice Artificial Respiration, if patient is not breathing well.

Colocynth—See Drastics.

Chloral Hydrate—No chemical antidote. If seen immediately after taking of poison give Emetics; if more than half an hour has elapsed emetics are more likely to do harm than good. *Keep the patient in a horizontal position*; try to prevent sleep.

Cocculus Indicus—See Picrotoxin.

Codeine—See Opium.

Colchicum—Give Emetics—Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls). Tannic Acid (20 grains) is of some value as an antidote.

Conium—Give Emetics—Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls), Lugol's Solution (10 drops) or Tannic Acid (20 grains). Artificial Respiration should be practiced if the patient shows signs of asphyxia.

Convallaria—See Digitalis.

Copper Sulphate or other copper salts—Potassium Ferrocyanide (Yellow Prussiate of Potash) (10 grains). Milk of Magnesia (1 tablespoonful) or White of Eggs is of some value if ferrocyanide is not at hand.

Cocaine—If taken by mouth, give Emetics or Lugol's Solution (10 drops) or Tannic Acid (20 grains).

Croton Oil—See Drastics.

Corrosive Sublimate—See Mercury Bichloride.

Cyanides—See Hydrocyanic Acid.

Digitalis—If the patient has not already vomited, give an Emetic. There is no chemical antidote known; treatment, aside from evacuation, in general, is of little avail.

Drastics—The drastic cathartics include **Colocynth, Gamboge, Croton Oil, Elaterin, Scammony, Jalap,** etc. If vomiting has not already occurred, give Emetics or Demulcents, Mucilage of Acacia (2 tablespoonfuls) or White of Eggs.

Elaterin—See Drastics.

Ergot—Give Emetic—Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls). No satisfactory antidote.

Eserine—See Physostigmine.

Ether—See Chloroform.

Fish-berries—See Picrotoxin.

Formaldehyde—Ammonia (Aromatic Spirits) (1 teaspoonful); Ammonia Water, U. S. P. (30 drops); Ammonium Carbonate (10 grains) well diluted. If the patient has not vomited, give Emetics.

Gamboge—See Drastics.

Fowler's Solution—See Arsenic.

Gas, Illuminating—See Carbon Monoxide.

Gelsemium—Treat same as Conium.

Hydrocyanic Acid—Treatment must be prompt, as this is one of the most quickly acting of poisons, indeed it is so quick that few remedies have time to act. Probably the most practically useful antidote is Solution of Hydrogen Dioxide (2 teaspoonfuls). Ferri Hydroxidum Cum Magnesii Oxido (one-half a tumblerful) has been recommended. Artificial Respiration, and Oxygen inhalations are also of service.

Hyoscyamus—Treatment same as Atropine.

Ignatia—See Strychnine.

Indian Hemp—See Cannabis.

Illuminating Gas—See Carbon Monoxide.

Iodine—Starch or Flour (2 tablespoonfuls) stirred up in water to make a paste. If the patient has not vomited, give Emetics.

Larkspur—Treat as under Aconite.

Lead Acetate or other lead salts—Magnesium Sulphate (Epsom Salt) or Sodium Sulphate (2 tablespoonfuls). As Emetic, preference is for Zinc Sulphate (20 grains).

Lye—See Alkalies.

Mercury Bichloride or other salts of Mercury—Give Emetic—Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls). The commonly recommended white of egg is of no value. Probably the best antidote is Fantus's Antidote; this is made as follows: Sodium Hypophosphite, 5 Gm., Solution of Hydrogen Dioxide, 25 cc., Water, 50 cc. (this is the amount to neutralize one antiseptic tablet (0.5 Gm.), if more has been taken the dose must be correspondingly increased); the stomach should be washed out afterwards. Carter's (or Linhart's) antidote consists of Sodium Phosphite (not hypophosphite or phosphate) and Sodium Acetate; it is efficient but as the first ingredient is not ordinarily found in drug stores is of small practical value. Calcium Sulphide (Calx Sulphurata) is also efficient but is poisonous of itself; it may be used when other remedy is not at hand in doses of not over 5 grains.

Methanol (Methyl Alcohol, Wood Alcohol, etc.)—Empty the stomach with Emetic. Follow by Sodium Bicarbonate (2 teaspoonfuls) in water; the soda should be repeated as it tends to neutralize the decomposition products of the poison in the system.

Morphine—See Opium.

Nux Vomica—See Strychnine.

Oil of Bitter Almond—See Hydrocyanic Acid.

Oils, Volatile, including Tansy, Rue, Cloves, Pennyroyal, etc., poison by their local irritant effects. Empty the stomach if the patient has not already vomited; afterwards give demulcents as Mucilage of Acacia (2 tablespoonfuls), or White of Eggs.

Oxalic Acid—See Acid, Oxalic.

Paris Green—See Arsenic.

Phenol—Give Emetics, preferably Zinc Sulphate (20 grains), follow with Magnesium Sulphate (2 tablespoonfuls); then with Mucilage of

Acacia (2 tablespoonfuls). *Avoid the use of oils or of alcohol.* External burns by phenol should be washed with alcohol.

Phosphorus—As Emetic, preference should be given to Copper Sulphate (5 grains), but if not at hand other emetics may be used. The chemical antidotes are Copper Sulphate or Potassium Permanganate (5 grains) in a tumblerful of water. *Avoid all oils or fats.*

Opium, Morphine or Codeine—If seen early give Emetics—Zinc Sulphate (20 grains); after narcosis has set in emetics fail to act. The best antidote is Potassium Permanganate (5 grains) in a tumblerful of water. Tannic Acid (20 grains), or Lugol's Solution (10 minims) may be used if the permanganate is not available. Keep the patient awake by shouting, do not use the commonly advised method of walking him; the best way of preventing sleep, if available, is the electric brush. If breathing becomes very low, practice Artificial Respiration.

Physostigma—Give Emetics—Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls). Chemical antidotes are Potassium Permanganate (5 grains) or Tannic Acid (20 grains). Artificial Respiration may become necessary.

Phytolacca—If the patient has not already vomited, give an Emetic—(Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls). There is no chemical antidote known.

Picrotoxin—Give Emetics—Zinc Sulphate (20 grains) or Mustard (2 teaspoonfuls). There is no known antidote. Chloroform may be used cautiously to control convulsions.

Potassium Cyanide—See Hydrocyanic Acid.

Potassium Hydroxide—See Alkalies.

Prussic Acid—See Hydrocyanic Acid.

Pilocarpine—If taken by mouth give Emetics. As antidote use Lugol's Solution (10 minims) or Tannic Acid (20 grains). Atropine is so valuable as a physiological antagonist that the pharmacist is justified in giving 1/100 grain without waiting for physician.

Rough on Rats—See Arsenic.

Silver Nitrate—Give Sodium Chloride (2 teaspoonfuls) in a glass of water. Follow by White of Egg.

Squill—Treat as under Digitalis.

Staphisagria—Give Lugol's Solution (10 minims). *Keep the patient in a horizontal position*; the drug acts much like Aconite but is not so dangerous.

Stramonium—See Belladonna.

Strophanthus—Treat same as Digitalis poisoning.

Tartar Emetic—See Antimony.

Veratrum Viride—Give Lugol's Solution (10 minims) or Tannic Acid (20 grains). *Keep the patient in a horizontal position;* do not allow him to arise to vomit; keep him warm. Artificial Respiration may be necessary.

Wood Alcohol—See Methanol.

Yellow Jessamine—Treat the same as Conium.

Zinc Sulphate or other Zinc Salt—Chemical antidote is an alkali; Sodium Bicarbonate (1 teaspoonful) or Sodium Carbonate (15 grains), well diluted; or the corresponding salts of potassium. After administering these follow with White of Egg or Mucilage of Acacia.

PART XVI

A LABORATORY COURSE IN MANUFACTURING PHARMACY AND DISPENSING

CHAPTER CXXIV

THE following outlines are offered as a suggestion for the teaching of manufacturing pharmaceutical processes and prescription compounding. Three courses are suggested in order to comply with the requirements of modern pharmaceutical education.

The outline of the first year starts with practice in the simpler technical operations, such as weighing, measuring, etc., with special emphasis upon efficient technic.

As this book discusses elsewhere not only the details of all processes, but also explains reactions, assays, and the individual preparations, no attempt is made to give other than the subjects for the lesson, and the points that must be covered, reference being made to the details found elsewhere in the book.

The *Pharmaceutical Syllabus, Third Edition*, has been taken as the basis for the instruction although its order of presentation is not followed. It is understood, of course, that each teacher should further elaborate upon the suggested instruction, so that there is ample opportunity for individuality of courses. Furthermore, methods of teaching may be varied, subject to the existing conditions.

A laboratory course usually involves preliminary explanation by the instructor. This is followed by practical work in the laboratory, carried out individually under careful supervision. The third step should be a complete report of operations, covering reactions if any are involved, and other essential features. Every lesson should be followed within a week by either an oral or a written review.

The instructor in the initial discussion should not cover every feature of the operation, but should expect the student to acquire much of the detailed information about every process through study or reading or by actual experience in the laboratory.

If an immense amount of technical information is given at the beginning of a lesson it fails to make a proper impression and may even detract from the interest. During the lesson the student should be given careful personal supervision and errors pointed out and corrected, without taking away too much initiative.

An absolute rule should be established that no preparations may be turned in for credit until they are satisfactory. Wherever possible there should be coördination in work between departments. For instance, drugs should be identified in the botanical laboratory; they should then be milled, if possible, with the assistance of advanced students. If chemicals are involved they should be, wherever possible, passed upon for quality in the chemical laboratory. When preparations have been made, those which are assayable should subsequently be checked up and the quality determined. Advanced students can be given practice in carrying out these tests and assays.

It has been found desirable to use a form for each lesson upon which the student makes out a report. This at least is applicable to the manufacture of Pharmacopœial or National Formulary preparations (see Fig. 803). It will be noted that this requires a student to examine the physical characteristics of the preparation, and this is considered an important part of the training. This can be supplemented from time to time by examination of specimens which are not labeled, the idea being to familiarize the student with the color, odor, and taste of many of the products he will handle so that when they are used in prescription filling it will constitute an additional check upon the accuracy of compounding.

Form for reporting manufacturing operations

There are certain points in laboratory teaching which may be mentioned to an advantage.

Apparatus — The apparatus named in Fig. 804 has been found satisfactory for the majority of the laboratory lessons, special apparatus, such as pill machines, suppository molds, tablet triturate molds, etc., being supplied as required for individual lessons.

The student is required to purchase a three-inch spatula since this can rarely be handed on to another student and is always useful.

The student is required to inspect this apparatus upon being assigned to his desk or working counter and sign a receipt for its perfect condition. The apparatus from that time until the end of the school year is under the care of the student, who keeps it in a locked closet. Any special apparatus loaned for an individual lesson is charged against the student and must be returned for credit.

At the close of the course, the complete set of apparatus must be returned at which time proper receipts are given by the stock clerk. An appropriate breakage deposit has been held by the clerk during the interim and the amount unexpended is returned to the student. This plan insures a complete set of equipment ready for the next year's work, but it must be inspected by the instructor before a release is given the student.

A balance of appropriate type and sets of apothecary and metric weights, should be separately loaned to the student, upon which he places a deposit. This deposit is returned in part at the close of the course. The practice followed has been to lend each student a new or rebuilt balance, to insure accurate weighing, and at the close of each year have all balances repaired or rebuilt by the manufacturer. This service has been supplied by the Henry Troemner Company of Philadelphia.

Neatness and Cleanliness—The student should be impressed with the importance of keeping apparatus, closet, and working area in a creditable condition of cleanliness and neatness. This should be verified by frequent inspection. In fact, the exterior of the working counter (or laboratory table), should be examined during and at the close of every lesson. This is not for the purpose of avoiding janitor service, but for proper training, as it is considered

FIG. 804

OPERATIVE PHARMACY LABORATORY

Receipt

.....19.....

The following articles were received in good condition by the undersigned for use in the Operative Pharmacy Laboratory and will be returned in equally good condition at the close of the school term or if compelled to leave school.

1 Key
1 Metric graduate 250 cc.
1 Metric graduate 15 cc.
1 Solution mortar and pestle
1 Pill mortar and pestle
1 Small funnel
1 Large funnel
1 Pint wide-mouthed bottle
1 Quart wide-mouthed bottle
2 Retort rings
1 Glass rod
1 Pint flask
1 Pint evaporating dish
6 (4-oz) wide-mouthed bottles
2 Test tubes
1 Water bath and wire frame
1 Bunsen burner
1 Wire gauze
1 Asbestos plate

Name .....

Desk Number.....

Receipt for minimum list of loaned apparatus

essential that all manufacturing and prescription filling should be as carefully carried out, from the standpoint of cleanliness, as is the preparation of foods or any other product involving health. Furthermore, a training in neatness is a factor in the development of care and accuracy.

Every student is required to supply himself with soap, a bottle brush, such as the Lenox brush (Fig. 597), and a towel. Laundry facilities should be provided so that the student can exchange a soiled towel for a clean one, at any time and at a nominal cost. This will be found a valuable adjunct to the rule for cleanliness.

First Year Pharmacy Laboratory Outline

The following outlines are presented without any attempt to divide them into lessons, it being recognized that the length of lesson periods varies greatly in different schools. It is left for the teacher to make the assignments to conform to the conditions.

Assign all desks. The student should inspect and give a receipt for all apparatus. This may be followed by a brief consideration of the several textbooks and laboratory guides required for the course. These should include the United States Pharmacopœia and the National Formulary and some other books which should be accessible for reference, such as a general textbook on pharmacy, a dispensatory, a good general formulary and such additional books as may be needed for the special work assigned.

Weighing

1. Construction and care of balances (pages 42 to 48).
2. Proper use of balances (page 47).
3. Metric weights for all manufacturing operations and for chemical analyses (pages 48 and 1431).
4. Apothecary weights for prescription filling (pages 48 to 50, and 1431).
5. Determine the weight by the metric system of various apothecary weights and likewise the equivalent in the apothecary system of various metric weights, noting especially the equivalent of the gram and the grain.
6. Weigh the following amounts of a powdered drug, such as glycyrrhiza: 1 gram (Gm.), 35 Gm., 0.1 Gm., 3.25 Gm., 0.01 Gm., 9.40 Gm., 0.06 Gm., and others.

   Also weigh 1 grain (gr.), 15.43 gr., 1 drachm (ʒ), 1 scruple (℈), 45 grains, $\frac{1}{10}$ grain, $\frac{1}{2}$ grain, and others.

Measuring Liquids

1. Method of holding and pouring from a graduate (page 53).
2. Reading the meniscus (page 53).
3. Measuring quantities from 10 cc. to 500 cc. (pages 51 and 53).
4. Measuring fractions of a cc. (page 53).
5. Graduate a pint wide-mouthed bottle into 50 cc. divisions, marking the graduations with a pencil, on an inch wide strip of adhesive plaster attached to the bottle.
6. Measuring large volumes (page 50).
7. Measuring minims (pages 53 and 214).
8. Comparison of quantities in metric and apothecary measures. Note the volume of 1 fluidounce (f ℥i) of water in cubic centimeters (cc.) (pages 77, 31, and 36).

   Note the comparison between 1000 cc. and 1 quart (pages 31 and 33). Make other comparisons to familiarize the student with other volumes.

Measuring Lengths

1. Measure the length of the desk and the width of the desk by the metric system, and also by the use of the ordinary system, using feet and inches (pages 31, 39, and 77).
2. Determine the length in millimeters (mm.), centimeters (cm.), and also in inches or fractions of inches, of a number of familiar objects such as a notebook, the diameter of a glass rod, the height of a graduate, etc.

Filtration

1. Filtering devices (pages 196 to 210).
2. Types of funnels and their proper use (pages 200 to 206).
3. Folding and using a paper filter (pages 197 to 199).
4. Filtering adjuncts, talc, kieselguhr, etc. (page 204).

Trituration

1. The use and method of handling various mortars:
   (a) Solution (pages 173 and 1651).
   (b) Trituration (pages 151 to 153).
   (c) Contusion (page 155).
   (d) Pill making (page 1691).
2. Reduce 10 Gm. of digitalis leaves to a fine (No. 60) powder (page 169).
3. Use a No. 60 sieve in the above operation (page 166).
4. Prepare a 10 per cent triturate of arsenic trioxide (page 485) with lactose as the diluent. Add 1 per cent of powdered Cudbear. The latter is of assistance in checking uniformity of distribution and accuracy of weight.

Evaporating Dish

1. Use of retort stands (pages 138 and 205).
2. Kinds of evaporating dishes and their use (pages 117, 118, and 129).

Bunsen Burners and Stoves—Devices for supplying heat (pages 98 to 101) (gas stoves, Bunsen burners, electric stoves, etc.). The regulation of heating devices should be practiced.

Baths—Use of sand baths, water baths, steam baths, etc. (pages 112 to 119).

Thermometers

1. Compare Fahrenheit and Centigrade thermometers (pages 91 and 102).
2. Practice in converting Fahrenheit (F.) degrees to Centigrade (C.) and *vice versa* (pages 91 and 103).
3. Check the freezing point temperature in melting ice and salt.
4. Check the boiling point reading of thermometers with the use of boiling water in a flask.

Absorption of Heat by Solution—Dissolve salt in water and note the diminishing temperature (page 172).

Evolution of Heat by Solution—Dissolve sodium hydroxide in water and note the rise in temperature (page 173).

Absorption of Heat by Evaporation—Evaporate a volatile liquid (chloroform or alcohol) from a dish and note the fall in temperature.

Melting Points—Determine the melting points of various substances (page 106).

Boiling Points—Determine the boiling points of several liquids, noting that the boiling point is always the same under uniform conditions (page 120).

Sublimation—Devise a suitable apparatus and sublime such substances as naphthalene and iodine (page 151).

Viscosity—Note the difference in the "body", or viscosity, of such liquids as ether, glycerin, liquid petrolatum, water, syrup, etc. Determine their exact viscosity if apparatus is available (page 1526). Illustrate the effect of changes in temperature upon viscosity.

Miscellaneous Technical Processes—The following individual operations should be taught in making the official or other preparations which follow:

Simple solution
Saturated solution
Compound solution
Crystallization
Granulation
Precipitation
Filtration
Clarification
Purification
Decoloration
Evaporation
Simple distillation
Percolation

Drug Store Packages

1. Properly wrap, label, and tie such substances as granular ammonium chloride, in packages of one ounce and four ounces (page 1673).
2. Discuss and demonstrate cartons as a desirable substitute for the old-style drug store package.
3. Properly cap, wrap, and tie, various sizes of bottles.
4. Wrap and tie pill and powder boxes and other small, odd-shaped packages.
5. Wrap and tie together a number of small packages.

   NOTE—For package wrapping, a paper of good quality, preferably on rolls, should be employed and also suitable twine. It is recommended that white paper be used for all small packages and either red or blue "druggists twine". For large packages Manila paper in sheets and heavier twine are best adapted (page 1673).

Waters—Definition, characteristics and preparations (pages 250 to 256).

1. Prepare 100 cc. of Camphor Water (page 253) without a distributing medium.

   NOTE—The camphor may be powdered by the addition of a drop or two of alcohol, which should be allowed to evaporate. Add 3.6 Gm. of sodium chloride to 10 cc. of the finished camphor water and agitate thoroughly. The camphor separates and provides an optical evidence of its previous solution in the water.
2. Prepare 500 cc. of Cinnamon Water using purified talc (page 254), as a distributing and filtering medium.
3. Prepare 500 cc. of Chloroform Water (page 253).
4. Prepare 500 cc. of Anise Water (page 252), using purified siliceous earth as the distributing and filtering medium.

Acids—Definition, characteristics, and preparation, page 552. Consider here only the dilution of stronger acids and the compound forms.

1. Note the strength and specific gravity of the official liquid acids, (pages 553 to 556).
2. Prepare 500 Gm. of Diluted Hydrochloric acid. Note especially that diluted acids are officially made by *weighing* the components. If measured, the specific gravity of the strong acid must be taken into consideration. A taring balance or a tare must be employed to counterbalance the vessel in which the acid and water are mixed.
3. Prepare 100 cc. of Diluted Nitrohydrochloric Acid (page 566). (Apply the official test for activity.) Note constituents in the finished acid and also the reaction involved (page 565).
4. Prepare 100 cc. of Aromatic Sulphuric Acid (page 565).

Mucilages—Definition and preparations (pages 285 to 287).

1. Prepare 100 cc. of Mucilage of Acacia by the official process (page 286).
2. Prepare 100 cc. of Mucilage of Acacia extemporaneously, using granular acacia, preferably. Powdered acacia may be used. In this process add a volume of water at the start, equal at least to the amount of acacia taken or all of the water may be added at the beginning. Unless sufficient water is added the acacia forms lumps and dissolves very slowly.
3. Prepare 100 cc. of Mucilage of Chondrus (page 286).
4. Prepare 100 cc. of Mucilage of Sassafras Pith (page 287).

Syrups—Definition and preparations (pages 261 to 284).

1. Prepare 500 cc. of Syrup (Simple Syrup) by the percolation process (page 265).
2. Prepare 500 cc. of Syrup by the hot process (page 265). Compare process and products, noting all advantages and disadvantages of each. Demonstrate preparation of syrup on a large scale by percolation (page 263).
3. Prepare 500 cc. of Syrup of Tolu (page 271).
4. Prepare 500 cc. of Syrup of Orange (page 266).
5. Prepare 500 cc. of Syrup of Wild Cherry (page 268).
   NOTE—This syrup may be reserved until the consideration of percolation if desirable.
6. Prepare 500 cc. of Compound Syrup of Hypophosphites (page 278).

Glycerites—Definition and preparations (pages 300 to 304).

1. Prepare 20 Gm. of Glycerite of Tannic Acid (page 300).
2. Prepare 50 Gm. of Glycerite of Boroglycerin (page 301).
3. Prepare 50 Gm. of Glycerite of Starch (page 300).

Elixirs—Definition and preparations (pages 315 to 339).

1. Prepare 500 cc. of Aromatic Elixir (page 315).
   NOTE—Preferably, before filtration, divide the mixture into two equal portions, adding purified talc to one and purified siliceous earth to the other. Make a comparison of the two filtering media. Note the advantage of combining oils for flavoring as in the Compound Spirit of Orange (page 308).
2. Prepare 200 cc. of Elixir of Gentian (page 327). Note the use of sodium citrate to avoid discoloration with iron.
3. Prepare 100 cc. of Elixir of Iron, Quinine and Strychnine (page 326).
   NOTE—Compare this with the unofficial Elixirs of the Phosphates of Iron, Quinine and Strychnine (page 338).
4. Prepare 100 cc. of the Compound Elixir of Pepsin (Compound Digestive Elixir) (page 331).

Mixtures—Definition and preparations (pages 291 to 297).

1. Prepare 100 cc. of Compound Mixture of Glycyrrhiza (page 291).
   NOTE—This is not to be filtered.
2. Prepare 100 cc. of Chalk Mixture (page 291).
3. Prepare 100 cc. of Compound Mixture of Rhubarb (page 296).

Liniments—Definition and preparations (pages 345 to 350).

1. Prepare 100 cc. of Soap Liniment (page 346).
2. Prepare 100 cc. of Lime Liniment (page 345).
3. Prepare 100 cc. of Camphor Liniment (page 345).
4. Prepare 100 cc. of Calamine Liniment (page 347).
5. Prepare 100 cc. of Acetic Turpentine Liniment (page 349).

Petroxolins—Definition and preparations (pages 351 to 354).
1. Prepare 100 cc. of Liquid Petroxolin (page 352).
2. Prepare 20 cc. of Iodine Petroxolin (10 per cent) (page 353).

Honeys and Oxymels—Definitions and preparations (pages 284 to 285).
1. Prepare 100 Gm. of Honey of Rose (page 284).
2. Prepare 25 Gm. of Honey of Sodium Borate (page 285).
3. Prepare 25 Gm. of Oxymel of Squill (page 285).

Confections—Definition and preparations (pages 488 to 489).
1. Prepare 25 Gm. of Confection of Rose (page 289).

Masses—Definition and preparations (page 487 to 488).
1. Prepare 50 Gm. of Mass of Ferrous Carbonate (pages 487 and 713).
2. Prepare 50 Gm. of Mass of Mercury (page 488).

Compound Powders—Definition and preparations (page 478).
1. Prepare 25 Gm. of Compound Chalk Powder (pages 478 to 484).
2. Prepare six (6) sets of Seidlitz Powders (page 478).
3. Prepare 50 Gm. of Compound Powder of Glycyrrhiza (page 479).
4. Prepare 25 Gm. of Rubefacient Spice Powder (page 482).

Triturations—Definition and type formulas (page 485).
1. Prepare 20 Gm. of a 10 per cent Triturate of Corrosive Mercuric Chloride.

NOTE—Have the instructor check ingredients and weighings.

Solutions—Definition and preparations (page 256 to 260).
1. Prepare 100 cc. of Antiseptic Solution (page 339).
2. Prepare 100 cc. of Alkaline Aromatic Solution (page 340).

NOTE—Solutions involving more complex chemistry will be taken up in the second year.

Spirits—Definition and preparations (pages 305 to 315).
1. Prepare 100 cc. of Aromatic Spirit of Ammonia (page 307).
2. Prepare 100 cc. of Spirit of Peppermint (page 310).

Infusions—Definition and preparations (page 357).
1. Prepare 500 cc. of Infusion of Digitalis (page 360).
2. Prepare 100 cc. of Compound Infusion of Senna (page 361).

Decoctions—Definition and preparations (page 362).
1. Prepare an unofficial decoction such as Cetraria, by the general formula.

Vinegars—Definition and preparations (page 449).
1. Prepare 100 cc. of Vinegar of Squill (page 449).

Tinctures—Definition and preparations (pages 364 to 401).
TYPE PROCESS P.
1. Prepare 500 cc. of Compound Tincture of Gentian (page 373).

TYPE PROCESS M.
1. Prepare 200 cc. of Tincture of Benzoin (page 368).
2. Prepare 100 cc. of Tincture of Sweet Orange Peel (use fresh fruit) (page 367).

Fluidextracts—Definition and preparations (pages 402 to 442)
TYPE PROCESS "A".
1. Prepare 100 cc. of Fluidextract of Rhubarb (page 414).

TYPE PROCESS "B".

1. Prepare 100 cc. of Fluidextract of Krameria (page 431).

TYPE PROCESS "C".

1. Prepare 100 cc. of Fluidextract of Gentian (page 428).

TYPE PROCESS "D".

1. Prepare 100 cc. of Fluidextract of Cascara Sagrada (page 408).
2. Prepare 100 cc. of Aromatic Fluidextract of Cascara Sagrada (page 408).

Extracts—Definition and preparations (pages 451 to 470).

1. Prepare Pilular Extract of Taraxacum using 200 Gm. of drug (page 469).
2. Prepare 50 Gm. of Powdered Extract of Cascara Sagrada (page 457).

Ointments—Definition and preparations (pages 502 to 512, and Chapter CVII).

1. Prepare 100 Gm. of Ointment of Rose Water (page 503).
2. Prepare 25 Gm. of Belladonna Ointment (page 503).
3. Prepare 50 Gm. of Stronger Mercurial Ointment (page 504).
4. Prepare 25 Gm. of Iodine Ointment (page 505).
5. Prepare 25 Gm. of Ointment of Phenol (page 506).
6. Prepare 25 Gm. of Sulphur Ointment (page 506).
7. Prepare 25 Gm. of Ointment of Zinc Oxide (page 507).
8. Prepare 25 Gm. of Stainless Iodine Ointment (page 509).
9. Prepare 25 Gm. of Ointment of Mercuric Nitrate (page 509).

Cerates—Definition and preparations (pages 512 to 514).

1. Prepare 50 Gm. of Compound Rosin Cerate (page 514).

Inunctions—Definition and preparations (page 512).

1. Prepare 25 Gm. of Compound Menthol Inunction (page 512).

Dermatologic Pastes—Definition and preparations (page 516).

1. Prepare 25 Gm. of Zinc Paste (page 517).

Poultices—Definition (page 517).

1. Prepare 50 Gm. of Cataplasm of Kaolin (page 517). Show the domestic method of preparing flaxseed poultices, mustard poultices, spice poultices, etc.

Specific Gravity—Definition and methods of determination (pages 55 to 69, and 78).

Specific Gravity is considered at the close of the first year to insure familiarity with many of the theoretical considerations involved.

1. Make a pycnometer, or specific gravity bottle, as follows (see Fig. 805):
   (a) Cut a piece of lead so that it *exactly counterbalances* the weight of a dry and clean pycnometer flask.
   (b) Pour distilled water into the flask, until it reaches a point midway on the neck, then determine the weight accurately. (Adjust the volume, if possible, so that it weighs an even number of grams.)
   (c) Adjust the temperature of about 1000 cc. of water, in a quart wide-mouthed bottle, to 25° C. (add hot water slowly to the bottle of cold water until the desired temperature is reached).

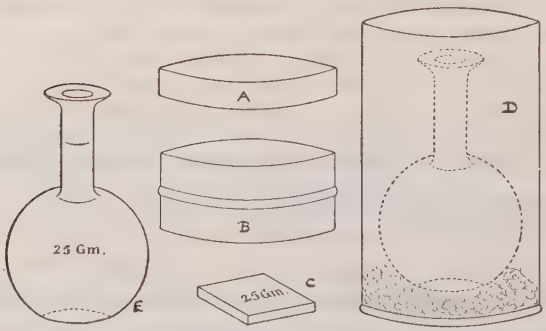
(d) Immerse the pycnometer flask of weighed water in the quart, wide-mouthed bottle of water, adjusted to 25° C. Keep it there for ten minutes.

(e) After sufficient time has been given to adjust the temperature of the water in the pycnometer, carry the flask of water, while yet in the water bath, to the main desk for graduation. Take with you to the desk a memorandum of the weight of water contained in the pycnometer so that this can also be marked on the flask. The assistant will then graduate the flask at the bottom of the meniscus, using a marking diamond, and also mark the weight of water on the flask.

(f) To complete the apparatus also stamp the lead weight with the amount of water which the bottle holds at 25° C., when filled to the graduation point.

(g) Finally wrap the finished pycnometer in cotton, and place it in the tin case.

FIG. 805



Specific gravity bottle, counterpoise, and case

2. Take the specific gravity of solution of ferric chloride at 25° C. Compare with the official requirements and estimate the comparative strength.
3. Take the specific gravity of simple syrup at 25° C. Compare with the official requirements and estimate the comparative strength.
4. Take the specific gravity of a sample of alcohol at the room temperature. Calculate the per cent of absolute alcohol, by volume, in the sample, using the U. S. P. alcoholometric table (page 909), and the temperature corrections (page 912).
5. Determine the per cent of absolute alcohol, by volume, in at least five different samples of dilute alcohol.
6. Determine the specific gravity of several liquids by weighing a glass stopper successively in water and in the liquid to be determined.
7. Determine the specific gravity of clean sand, using the pycnometer.
8. Determine the specific gravity of granulated sugar, using the pycnometer and oil of turpentine of known specific gravity, in place of water.
9. Determine the specific gravity of several liquids both heavier and lighter than water, by the use of hydrometers.

Second Year Pharmacy Laboratory Outline

Working desks and apparatus should be issued and receipted for as outlined for the first year.

The lessons of the second year begin with the more difficult official preparations, especially those requiring the understanding of chemical reactions.

Drugs which are to be used in preparations during this year or in the senior year should be purchased unground, and they should then be identified and passed upon for U. S. P. quality by advanced students, who should assay them if necessary. The drugs should then be ground in the college drug milling plant, under the direction of advanced students.

Preparations made by the second year students, and requiring assay, should be standardized by students of the third year.

Acids—Prepare 100 Gm. of Diluted Nitrohydrochloric Acid (page 555).

Syrups—Prepare 100 cc. of Syrup of Ferrous Iodide (pages 267 and 718).

Solutions

1. Prepare 100 cc. of Solution of Ammonium Acetate (page 652).
2. Prepare 100 cc. of Solution of Iron and Ammonium Acetate (page 722).
3. Prepare 100 cc. of Compound Solution of Cresol (page 814).
4. Prepare 100 cc. of Crude Solution of Cresol (Creolin type) (page 815).
5. Prepare 100 cc. of Solution of Ferric Chloride (page 714).
   NOTE—This solution should be tested for absence of ferrous salts and nitrate. It should also be assayed by advanced students and adjusted to conform to the U. S. P. specific gravity and strength (page 715).
6. Prepare a bottle of Solution of Magnesium Citrate (page 666).
7. Prepare 100 cc. of Solution of Lead Subacetate (page 738).
8. Prepare 100 cc. of Solution of Potassium Arsenite (page 766).
9. Prepare 100 Gm. of Solution of Chlorinated Soda (page 569).
10. Prepare 100 cc. of Solution of Sulphurated Lime (page 681).
11. Prepare 100 cc. of Compound Solution of Chlorine (page 573).
12. Prepare 100 cc. of Surgical Solution of Chlorinated Soda (Modified Dakin's Solution) (page 570).
13. Prepare 100 cc. of Solution of Ferric Citrate (page 725).
14. Evaporate and scale ½ of the solution of Ferric Citrate just prepared (page 725).
15. Prepare 100 cc. of Solution of Aluminum Acetate (page 702).
16. Prepare 100 cc. of Compound Solution of Sodium Borate (page 641).
17. Prepare ⅕ of the official formula for Solution of Calcium Hydroxide (page 672).
18. Prepare 25 cc. of Solution of Potassium Citrate (page 608).

Effervescent Salts—Definition and preparations (pages 475 to 477).

1. Prepare 100 Gm. of Effervescent Magnesium Sulphate (page 670).
2. Prepare 100 Gm. of Effervescent Artificial Vichy Salt (page 477).

Tinctures—Prepare 100 cc. of Tincture of Belladonna (page 367).

NOTE—This tincture is to be assayed by advanced students and adjusted to conform with the U. S. P. standard.

Prepare 100 cc. of Tincture of Digitalis (page 372).

NOTE—This tincture is to be assayed biologically by advanced students and the volume adjusted to conform to the U. S. P. standard.

Fluidextracts

1. Prepare 100 cc. of Fluidextract of Cinchona (page 409).
   NOTE—This fluidextract is to be assayed by advanced students and the finished product adjusted to conform to the U. S. P. standard. The alcohol per cent also is to be determined, using the official process (page 908).

Extracts

1. Prepare 50 Gm. of Extract of Nux Vomica (page 462).
   NOTE—This extract is to be assayed by advanced students and the finished product adjusted to conform to the U. S. P. standard.

Spirits

1. Prepare ethyl nitrite by the U. S. P. 1890 method (pages 305 and 919), and using the ester produced, prepare official Spirit of Ethyl Nitrite.
   NOTE—Preserve at least 1 ounce of this spirit as directed by the Pharmacopœia (page 920). A portion of the product should be assayed by advanced students and the report entered as a part of the record.

Oleoresins—Definition and preparations (pages 445 to 447).

1. Prepare Oleoresin of Cubeb, using 100 Gm. of drug (page 447).

Resins—Definition and preparations (pages 471 to 473).

1. Prepare Resin of Podophyllum, using 100 Gm. of drug (page 473).
   NOTE—The resin should be assayed by advanced students and the result entered upon the records.

Soft Soap—Prepare 100 Gm. of Soft Soap (page 1055) and test for alkalinity.

Magmas—Definition and preparations (page 297).

1. Prepare 100 cc. of Magnesia Magma (page 664).
2. Prepare 100 cc. of Bismuth Magma (page 774).
3. Prepare Arsenic Antidote (page 717).

Magistral Pharmacy—Following the lessons in the manufacture of pharmaceutical preparations, the second year students should be given an opportunity to practice the technic required for extemporaneous pharmacy, usually called *magistral pharmacy*. Many of the operations are required in prescription filling but it is considered desirable to train the student in the technic of these operations before applying them to dispensing.

Emulsions—The student should be taught the English method, the Continental method and the "Forbes", or bottle, method for the preparation of emulsions and the advantages, limitations, and applications of each (pages 1655 to 1661).

1. Prepare the U. S. P. Emulsion of Cod Liver Oil (pages 288 and 1658).
2. Prepare the N. F. Emulsion of Cod Liver Oil with Egg (page 289).
3. Prepare a 50 per cent Emulsion of Cod Liver Oil, using the U. S. P. proportions of oil and acacia but following the English method (page 1657).
4. Prepare a 50 per cent Emulsion of Cod Liver Oil, with 4 per cent of acacia and 1 per cent of tragacanth, using the English method.

5. Prepare a 50 per cent Emulsion of Cod Liver Oil, with 12 per cent of powdered milk (Klim), using the English method.
6. Prepare a 25 per cent Emulsion of Castor Oil, with 7½ per cent of acacia, using the English method. Add methyl salicylate to flavor.
7. Prepare the N. F. Emulsion of Castor Oil (page 290).
8. Prepare the N. F. Emulsion of Petrolatum (page 290).
9. Prepare the U. S. P. Emulsion of Oil of Turpentine (page 288).
10. Prepare the U. S. P. Emulsion of Asafetida (the asafetida may be replaced by ammoniac) (page 287).
11. Prepare the N. F. Emulsion of Cod Liver Oil with Hypophosphites (page 289).

Suppositories—Thorough training should be given in the making of rolled or hand-made suppositories and also in the preparation of fused or molded suppositories (see page 1733).

Fused or molded suppositories—(Using Oil of Theobroma).

1. Prepare adult, rectal suppositories each containing 5 gr. of quinine sulphate.
2. Prepare adult, rectal suppositories each containing 5 gr. of ichthyol.
3. Prepare adult, rectal suppositories each containing 0.1 Gm. of tannic acid.
4. Prepare adult, rectal suppositories each containing 0.125 Gm. of tannic acid and 0.125 Gm. of extract of stramonium.
5. Prepare adult, rectal suppositories each containing 0.02 Gm. of extract of belladonna and 0.06 Gm. of lead acetate.
6. Prepare adult, rectal suppositories each containing 3 per cent of phenol. Use sufficient spermaceti to harden the suppository.
7. Prepare U. S. P. Glycerin Suppositories (page 523).

Fused or molded suppositories—(Using Glycerinated Gelatin).

1. Prepare vaginal suppositories, each of 10 Gm. weight, using the following formula.

Zinc Oxide	1.0 Gm.
Boric Acid	0.5 Gm.
Water	3.0 cc.
Glycerin	6.6 Gm.
Glycerinated Gelatin	10 Gm.

2. Prepare vaginal suppositories, each of 10 Gm. weight, containing 50 per cent of glycerite of boroglycerin.

Hand-made or rolled suppositories—(Using Oil of Theobroma). Try the making of rolled suppositories without dusting powder, also separately try powdered starch, and lycopodium.

1. Prepare rectal, cone-shaped, suppositories of adult size from any convenient suppository formula, or one suggested for molded suppositories.
2. Prepare suppositories similar to No. 1 but of infant size.
3. Prepare adult, rectal, suppositories, shaped as recommended by Wellcome (see page 1737).
4. Prepare vaginal suppositories, weighing 4 Gm. each.

Troches (see pages 498 and 1697).

1. Prepare the U. S. P. cut Troches of Ammonium Chloride (page 498).
2. Prepare the N. F. cut Troches of Elm (page 499).
3. Prepare the U. S. P. IX cut Troches of Cubeb (page 499).
4. Prepare 100 troches from the following formula, rolling the mass into a pill pipe or cylinder, cutting it into sections about twice the length of the diameter:

Menthol	0.1 Gm.
Benzoic acid	0.3 Gm.
Powd. Ext. of Glycyrrhiza	32.5 Gm.

Make into 100 troches.

Powders—The general subject of official compound powders and also triturations has been considered in the first year. At this point, the technic of dividing and folding powdered substances, extemporaneous dispensing, is to be taken up (page 1675).

1. Prepare 12 powders, each containing 1/10 gr. of calomel and 1 gr. of sodium bicarbonate. Triturate thoroughly and using a spatula, form the powder into a rectangular block, divide into 12 squares, transfer each to a powder paper, and fold, using a powder folder.
2. Prepare a mixture containing 1½ dm. each of saccharated pepsin and sodium bicarbonate to which is added 1 drop of oil of peppermint. Distribute this directly upon 12 waxed powder papers (or instead of waxed papers use parchment papers or paraffin papers inside of ordinary powder papers). Fold these, using the powder box which is intended for dispensing.

Cachets (page 1685).

1. Prepare 6 cachets, using two wide-mouthed bottles for sealing, and a moistened filter paper as a moistening pad. Each cachet is to contain 5 gr. of acetylsalicylic acid.
2. Prepare 12 cachets, each containing 3 gr. of quinine dihydrochloride, using a cachet machine.

Capsules

Hard capsules (page 1678).

1. Prepare a mass from 3 Gm. of powdered aloes, and 2 Gm. of powdered sugar. Roll into a cylinder on a pill machine, cut into 12 sections, and insert into No. 2 hard capsules. (Be careful to avoid the soiling of the exterior of the capsule.)
2. Prepare 12 capsules, each containing 2½ gr. of quinine sulphate and 2½ gr. of phenyl salicylate. Mix the powders thoroughly in a mortar, reducing them to a fine powder, and fill into No. 1 hard capsules, seeing that each is of correct weight. Clean the capsules by dropping them into granulated sugar in a box, shaking thoroughly and separating.
3. Mix 4 cc. of oil of turpentine with 5 Gm. of starch, by trituration in a mortar. Then add water, drop by drop, with trituration, until the mass becomes pulverulent. Insert into 12 No. 1 hard capsules.
4. Fill 1 dozen No. 1 hard capsules with oil of turpentine, using a medicine dropper and sealing the capsules with hot water or diluted alcohol.

NOTE—Dip the top of the capsule into the sealing liquid to a depth of about only 1.5 mm. (1/16 inch).

Soft elastic capsules (page 1681).

1. Fill 12 (15 min.) soft elastic capsules with cod liver oil and seal with a hot solution of gelatin, made by dissolving 3 parts of gelatin in 2 parts of glycerin and adding enough water for the proper consistence. A loop of galvanized wire should be used for the sealing, the size of the loop corresponding to the opening in the capsule. In filling the capsule use a medicine dropper or a burette, wiping clean the exterior of the point with cotton each time before inserting it into the capsule.

Enteric capsules (page 1683). Capsules treated with formaldehyde are also called "*glutoid capsules*".

1. Incorporate 2.4 Gm. of monohydrated sodium carbonate with 1.2 Gm. of prepared suet and 0.6 Gm. of paraffin, without heat, by massing them in a mortar, and divide the mass equally between 12 No. 2 hard capsules.

   NOTE—It is claimed that this mixture will pass through the stomach because of insolubility and dissolve in the intestine.

2. Prepare 12 hard capsules each containing 5 gr. of sodium phenolsulphonate. Seal with hot water and immerse for exactly 30 seconds in a 1 per cent solution of formaldehyde. Remove the capsules immediately and dry. Hold for two weeks and test for their enteric quality, as suggested below.
3. Salol coating. Coat 12 filled capsules with phenyl salicylate, as directed on page 1731. See that the ends of the capsules are completely covered and caution the patient to avoid pressing the capsule, as the elastic walls are likely to cause the breaking of the coating.

Test Capsules—Always prepare several test capsules, each containing a small amount of calcium sulphide and methylene blue, and treat these by whatever method is employed for rendering the capsule enteric and do it at the same time. These test capsules are to be administered to prove their enteric character. If they dissolve in the stomach, the taste of sulphide is at once apparent. If the sulphide taste is absent, there is reasonable indication that the capsule has not dissolved in the stomach. A bluing of the urine is proof of its subsequent solution in the intestines. If both are absent the capsule has been proved to be completely insoluble.

Pills (see pages 489 and 1691).

1. Prepare 50 Pills of Ferrous Carbonate (page 490) using the pill tile. Shape the pills with the fingers.
2. Prepare 50 Compound Pills of Mild Mercurous Chloride, cutting and shaping the pills on a pill machine without reshaping by hand.
3. Prepare 50 Pills of Phosphorus, coating the pills with tolu (page 491).
4. Prepare 24 Pills of Silver Nitrate, using the following formula:

Silver nitrate	0.8 Gm.
Kaolin	1.6 Gm.
Hardened petrolatum[1]	0.8 Gm.
Rosin cerate	0.2 Gm.

[1] Hardened petrolatum:

Yellow petrolatum	2 parts
Paraffin	1 part

Melt together and cool.

5. Prepare 48 pills from the following formula:

Aloes	75 gr.
Extract of belladonna	6 gr.

6. Prepare 24 *white* pills, each containing 2 gr. of quinine sulphate.

Pill Coating

1. Coat 25 of the Pills of Ferrous Carbonate already prepared, using silver leaf (see page 1721).
2. Coat 25 of the Compound Cathartic Pills already prepared, using phenyl salicylate (see page 1731).

Molded Tablet Triturates (see page 1701).

1. Prepare unmedicated tablet triturates, using a mixture of 1 part of sucrose and 5 parts of lactose, and moistening with a mixture of alcohol 7 parts and syrup 1 part. Dry the tablets and determine their weight as the basis for subsequent formulas.
2. Prepare 100 tablet triturates each containing 1/20 gr. of arsenic trioxide. Use as the diluent a mixture of 1 part of sucrose and 5 parts of lactose. Moisten with 90 per cent alcohol or a mixture of alcohol 7 parts and syrup 1 part. Dry the finished tablets.
3. Prepare tablet triturates each containing ½ min. of tincture of aconite. Add the tincture to a proper quantity of the sugar mixture, made as before. Distribute uniformly and dry without heat. Moisten the dry powder with the alcohol and syrup mixture, mold, and dry the tablets.

Compressed Tablets (see pages 500 and 1704 to 1712)—Study and set up the several types of tablet machines.

1. Prepare 5 gr. tablets of granular sodium bromide, using a hand compression machine, consisting of a cylinder and punches, and produce the compression by the blow of a mallet.
2. Prepare 5 gr. tablets of commercial granular potassium chlorate without further granulation, using a small power tablet machine like the Eureka (page 1709).
3. Prepare several granulations, using formulas on pages 1712 to 1719, and make tablets on a hand, and also on power machines, if available.

Plasters (see pages 518 and 1751 to 1755).

1. Spread a cantharides plaster suitable for behind the right ear, spreading it upon adhesive plaster, the student drawing and cutting the pattern from "tag" board, or a similar hard-surfaced flexible card.
2. Spread a back plaster, using "Burgundy pitch" plaster. Make the plaster about 4 by 6 inches. Spread it upon adhesive plaster or "tag" board, using a large spatula. The student should prepare the pattern.

Second Year Dispensing

The student having been taught the manipulative technic for most of the magistral operations required in dispensing, it is now appropriate to consider the professional responsibilities and duties of the dispenser. The term "*professional pharmacy*" has been subjected to severe strain during the rapid commercial development of modern drug stores. The difference between professional service and purely mercantile activities should be clearly understood. This is discussed in Chapter XCVI, under "*Filling the Prescription*", and the student who would aspire to the highest professional pharmaceutical service,

the intelligent and conscientious filling of prescriptions, must be imbued with the ideals of pharmacy and should make every effort to secure training and experience in its practice. The chapter on *"Filling the Prescription"* should be carefully studied before any prescriptions are filled in this dispensing course.

When the correct attitude of mind and the deep sense of responsibility which must be assumed by the pharmacist when filling prescriptions has been understood, the student may proceed to fill prescriptions. The prescriptions first filled should involve no serious complications. They are to be given for the purpose of thoroughly grounding the beginner in prescription routine. Every point of the technic of dispensing, as explained in Chapter XCVI, should be strictly maintained. The amount of time to be devoted to dispensing in this preliminary study, and the actual prescriptions to be filled, must be determined by the instructor in charge of each laboratory. Typical prescriptions will be found on pages 1804 to 1819, and these may be supplemented by others from the files of nearby pharmacies.

Third Year Pharmacy Laboratory Outline

During the third year the pharmacy student, who has already received the fundamental instruction in practically all pharmaceutical technic, should be given opportunity to coördinate the training in the various departments in the college, all of which is required in the proper selecting of materials, in the handling of pharmaceutical machinery, and in the ultimate production and standardization of products.

Pharmaceutical Control of Manufactured Products—The Chapter on a Control Laboratory (see page 1577) describes the responsibilities which must be assumed by the trained manufacturing pharmacist. He is called upon first to develop suitable formulas for the particular preparations required. Frequently this calls for experimental production on a smaller scale, before the formula is satisfactory. This applies to preparations which are unofficial, although many official processes require modification for large-scale production.

The formula having been satisfactorily developed, the ingredients must then be ordered, market conditions and business acumen being a factor in the purchase.

When the stock is received it must be approved; vegetable or animal drugs being passed upon by the experts in the botanical laboratory, the student conducting the examination under proper supervision.

If the materials needed are chemicals they must also be passed upon by the student in the chemical laboratory, the necessary tests and assays being applied. Drugs which are assayable must also be tested chemically (see page 1485) or biologically (see page 1503).

Having approved the ingredients, the drugs must be milled, if necessary, and then the preparation is made.

After the product is manufactured, again the skill of the pharmacist or chemist is called upon to pass upon the completed product and this frequently involves some form of assay.

The preparation is not complete without a final report upon the total and unit cost of the finished product in which due consideration must be given to the overhead cost.

This broad viewpoint of the manufacturing laboratory problems will develop skill in managing and should be carried out as far as practicable in the manufacture of elixirs, official solutions, emulsions, tinctures, fluidextracts, extracts, suppositories, and in the production of tablets, both plain and coated.

It is not necessary here to indicate any specific formula as any of the official preparations or the formulas for tablets (see page 1704) are suitable and may be selected as convenient by the instructors.

Frequently the products of large-scale manufacture may be disposed of through a local hospital, and perhaps much of the raw material will be supplied by the hospital, the finished product, after final approval, being turned over for hospital use. In this way, the cost of a course of this type is greatly reduced.

Pharmaceutical Journal Seminar—Each month throughout the third year each member of the class should be assigned a current pharmaceutical journal for review. A feature of the review should consist of the preparation of an abstract of several leading articles. These should be read before the group and handed in for correction and rating. They should be systematically written up on 5 × 8 inch index cards, and should include the title of the article, the author's name, and the name of the journal, with the year, and page number. The abstract should be signed by the student.

In the seminar, students should briefly describe the scope and field of the journal reviewed. Journals reviewed should cover the following fields: Professional pharmacy, commercial interests, journals covering both fields popularly, medical journals, like the *Journal of American Medical Association*, and *Hygeia*, chemical journals, like the *J. A. C. S.*, and the *Journal of Industrial and Engineering Chemistry*, journals of the perfumery and soap trade, foreign pharmaceutical journals, State association journals, and house organs. These reviews should be presented by the students at a regular seminar period.

Library Assignments—A regular feature of certain laboratory operations should be the specific assignment of a subject to each student who is to proceed to the library and make a careful review of the standard books and journal articles dealing with the subject. Attention should be called to, and the student should use, the "Digest of Comments on the U. S. P. and N. F.," prepared by the Hygienic Laboratory and also to the "Year Book of the A. Ph. A." These abstracts of literature should be presented by the student before the class and should be also written up and handed in.

Advanced Dispensing—The third year student should be given an opportunity in the latter part of the year to study prescriptions involving difficult manipulation or incompatibilities, demanding broad knowledge and excellent judgment.

The prescription should be placed in the hands of the dispenser without advice or suggestion, the filling of the prescription being accomplished through the initiative of the student alone. A complete report should be required and the finished product and the method of procedure subjected to group discussion. The aim of this course is to develop initiative and the ability to independently study the complicated problems often met in dispensing. Prescriptions may be selected from those on pages 1804 to 1819 for this study.

Sterilization (see pages 1779 to 1803).

1. Test the flasks and ampuls for the insolubility of the glass and their suitability for use with sterilized liquids. Follow the directions of the N. F., given on page 1791.
2. Sterilize the following glass apparatus, but first thoroughly clean, plug the flasks with non-absorbent cotton, and wrap in paper. Use dry heat for 2 hours at a temperature of 170° C.
    1. Insoluble glass flasks of 1 pint capacity.
    2. Insoluble glass ampuls of 5 cc. and 1 cc. capacity.

3. Sterilize the following pieces of apparatus in an autoclave, wrapping each outfit in a clean towel:
   1. Büchner funnel.
   2. Berkefeld-type filtering outfit (see Fig. 780).
   3. Burette, graduated in $\frac{1}{10}$ cc. divisions, with glass stopcock, and with rubber connections for a needle to be attached to the burette (see Fig. 781).
   4. Glass mortar and pestle.
   5. Glass funnels.
4. Prepare 500 cc. of physiological solution of sodium chloride, and filter it through a Büchner filter, using a hard paper filter. The solution must be filtered into an insoluble glass flask which has been previously sterilized. The solution must be free from all foreign particles or filaments. The sterilization should be conducted in an autoclave, under steam pressure and for thirty minutes after the temperature in the flask has reached 115° C. The flask should be closed with non-absorbent cotton, wrapped in gauze.
5. Prepare 500 cc. of sterilized, freshly distilled water, using a sterilized insoluble glass flask, and boiling at 100° C. for one hour. The flask must be closed with non-absorbent cotton which has been wrapped in gauze.
6. Prepare 25 (1 cc.) ampuls, each containing 1 gr. of green ferric citrate, in sterile aqueous solution, using the sterile outfit already prepared and the sterile ampuls. Sterilize the sealed ampuls and then label each ampul. Prepare other solutions (see pages 1795 to 1803).
7. Prepare 5 cc. ampuls of sterilized distilled water.
8. Test representative ampuls for sterility (see page 1794).

Perfumery and Cosmetics—Students in the third year should be given an opportunity to prepare some of the simpler perfumes and cosmetics. (See Perfumery, pages 1207 to 1243.) The laboratory work should be accompanied by a suitable study of the entire subject of perfumery so that the student will be qualified to discuss the history and the basic materials employed in perfumery. This materially assists in giving advice to customers and increases selling ability.

It is possible for the student to manufacture small lots of almost all varieties of perfumes. These should include concentrated perfume extracts, toilet waters, colognes, sachets, face creams of all kinds, face powders, talcum powders, hair preparations, especially shampoos, cuticle specialties, shaving cream, hand lotions, depilatories, etc.

It is not economically practicable for many of the basic perfume oils to be prepared by students, but formulas should be given and concentrated perfume oils, prepared by these formulas, may be used in perfuming some of the products. Other basic perfume oils of the more common type, as purchased upon the open market, should also be used by the class. The products of at least a half-dozen firms should be available for comparison.

PART XVII

CHAPTER CXXV

GLOSSARY

OF

UNCOMMON PHARMACEUTICAL AND TECHNICAL NAMES, TERMS, OR SUBSTANCES

A.

Abasier. Animal charcoal.
Abercrombies Lotion. Infusion of tobacco, 1 : 200.
Abric. Sulphur.
Acetum Acerrimum. Concentrated acetic acid.
Bezoardicum. Aromatic vinegar.
Saturni. Solution of lead subacetate.
Theriacale. Aromatic vinegar.
A. C. E. Anesthetic mixture of 1 volume of absolute alcohol, 2 volumes of chloroform and 3 volumes of ether.
Acid, Apple. Malic acid.
Azotic. Nitric acid.
Battery. Sulphuric acid and potassium dichromate.
Boroboracic (Acid Boroboric). Mixture of equal parts of borax and boric acid.
Borussic. Prussic. Hydrocyanic.
Carbazotic (Picronitric acid). Picric acid.
Catholicon. Sulphuric acid.
Cetylacetic. Stearic acid.
Chlorazotic. Aqua regia.
Dioxysuccinic. Tartaric acid.
Dipping. Sulphuric acid.
Electrolyte. Sulphuric acid.
Lithic. Uric acid.
Nancic. Lactic acid.
Orthoboric. Boric acid.
Phenic. Carbolic acid.
Phenylformic. Benzoic acid.
Pickling. Sulphuric acid.
Sozoiodolic. Diiodoparaphenolsulphonic acid. (Antiseptic.)
Sozolic. Orthophenolsulphonic acid.
Stearophanic. Stearic acid.
Sugar. Oxalic acid.
Sulphhydric. Hydrogen sulphide. Sulphuretted hydrogen. Hydrosulphuric acid.
Thiolinic. Sulphurated and sulphonated linseed oil.
Acid, Tumenolsulphonic. Obtained by treating the distillate of a mineral oil with sulphuric acid.
Vinegar. Acetic acid.
White. A mixture of hydrofluoric acid and ammonium bifluoride, used for etching glass.
Acidum Chloronitrosum. Nitrohydrochloric acid.
Cœruleum (Blue acid). Hydrocyanic acid.
Muriaticum Oxygenatum. Chlorine.
Nitrico-Nitrosum. Fuming nitric acid.
Ossium. Glacial phosphoric acid.
Scytodepsicum. Tannic acid.
Actol. Silver lactate.
Acusto. Potassium nitrate.
Adeps Anserinus. Goose grease.
Gadi. Cod liver oil.
Ovillus. Mutton suet.
Adipsos. Licorice.
Adragante. Tragacanth.
Aer Fixus. Carbonic acid gas.
Aerosus Lapis. Lapis calaminaris.
Ærugo. Crude copper acetate.
Æs. Copper.
Æs Aeratum. Copperas.
Æther Vegetabilis. Acetic ether.
Æthiops Antimonialis. Chiefly a mixture of black antimony and mercury.
Martialis. A black iron oxide; formed by keeping iron filings covered with water for a long time.
Mineralis. Mixture of mercuric sulphide and sulphur.
per se. Mercury oxide.
Vegetabilis. Charcoal of seaweed.
Affium. Extract of poppy-heads (opium).
African saffron. Carthamus.
After-damp. Carbon dioxide in mines following fire damp explosions.
Alabastic. A variety of gypsum.
Alabastine. An improved calcimine.
Alanin-Mercury. Mercury amidopropionate.
Albocarbon. Naphthalene.

Album Græcum. Excrement of dogs.
Nigrum. Excrement of mice or rats.
Alcohol Sulphuris. Carbon disulphide.
Alcoolat (French). A distilled spirit.
Alcoolature (French). An alcoholic tincture of a fresh plant. ("Green tinctures".)
Alcoolé (French). An alcoholic solution of a substance entirely soluble in the alcohol.
Alegar. Ale vinegar. (Made by fermenting ale upon raisins or vine cuttings.)
Algaroth, Powder of. Antimony oxychloride.
Alkali, Vegetable. Potassium carbonate.
Volatile. Ammonium carbonate.
Aloxite. Artificial oxide of alumina.
Alum, Cake. Aluminum sulphate.
Concentrated. Aluminum sulphate.
Cube. Potassium alum.
Patent. Aluminum sulphate.
Porous. Sodium aluminum sulphate.
Rock (Alumen Rupeum). Lump alum as it occurs with the earth attached.
Roman. See Rock Alum.
Alumen Plumosum. Asbestos.
Rubrum. Rock salt.
Alundum. Artificial aluminum oxide.
Amadou. Punk; tinder.
Ambretta Seeds. Musk seeds.
Amianthus. Asbestos.
Amidon. Starch.
Amino-Mercuric Chloride. Ammoniated mercury.
Ammonium Carbonicum Pyro-Oleosum. A mixture of ammonium carbonate with "animal oil".
Sulpho-Ichthyolate. Ichthyol.
Amphion. Opium.
Amplosia. An unfermented juice of the grape.
Amylhydride. Pentane.
Amylit. A trade name for an enzymic preparation used in the textile industry.
Amylodextrin. Soluble starch.
Analgesine. Antipyrin.
Anaphromeli. Clarified honey (Mel despumatum).
Angioneurosin. Nitroglycerin.
Anima Articulorum (Life of the Limbs). A name given to colchicum.
Rhei. Aqueous tincture of rhubarb.
Annidalin. Aristol. (Antiseptic.)
Anodynin. Antipyrin.
Anthion. Potassium persulphate.
Anthos (Flores or Herba). Rosemary (flowers or herb).
Anthrakokali. Coal treated with caustic potassa.
Anthrarobine. Dioxyanthranol. Leucoalizarin. (Antiseptic dermic.)
Antidotum Fuchsi. Hydrated ferric oxide (Arsenic antidote).
Antifungin. Magnesium borate.
Antihypo. Potassium percarbonate.
Antimonine. Antimony lactate.
Antimonium Album. Bismuth.
Antimony, Diaphoretic. Potassium antimonate.
Antimony, Needles. Antimony sulphide.
Antisepsin. Monobromacetanilid. Paramonobromphenylacetamide.
Antiseptol. Cinchonine iodosulphate.
Ant Oil, Artificial. Furfural.
Antlia Gastrica. Stomach pump.
Apple Oil. Amyl valerate.
Apyonin. French designation for yellow pyoktanin. (Antiseptic.)
Apyrothium. Sulphur.
Aqua Adstricta. Ice.
Ærata. Carbonated water.
Æris Fixi. Carbonated water.
Binelli. Creosote water.
Bullientis (Aquæ). Boiling water.
Cerasorum. Diluted bitter almond water.
Coloniensis. Cologne water.
Communis. Common water, tap water.
Crotonis. Water from Croton Lake, New York (that is, hydrant water).
Flava. Yellow wash.
Fluvialis. River water.
Fontana. Spring water.
Fœtida Antihysterica. A distillate from asafetida, galbanum, myrrh, valerian, etc.
Gaseosa. Carbonated water.
Gummosa. Diluted mucilage of gum arabic (about 1 part of gum in 64 of water).
Hydrothionica. Sulphuretted hydrogen water.
Laxativa Viennensis. Compound infusion of senna. (Modified black draught.) (Also known as Elixir Lax. Vien.)
Marina. Sea water.
Artefacta. Artificial sea water.
Maris, Arte Paranda. Artificial sea water.
Metallorum. Mercury.
Mineralis. Mineral water.
Naphæ. Orange flower water.
Nigra. Black wash.
Nivalis. Snow water.
Phagedænica. Yellow wash.
Pluvialis. Rain water.
Pura. Distilled water.
Saturnina. Lead water.
Vitæ. Brandy or whisky.
Aquila Alba. Calomel.
Arcanum Duplicatum. Potassium sulphate.
Argentum Fugitivum. Quicksilver.
Musivum. Mosaic gold. Tin bisulphide.
Vivum. Quicksilver.
Argilla. Clay. (In pharmacy it means alumina.)
Sulphurica Alcalisata. Alum.
Arquebusade. An agreeably smelling vulnerary water, which might be called "compound sage water".
Art Metal. An alloy of copper, tin and lead.

Asa Dulcis. Benzoin.
Asaprol. Calcium salt of betanaphtolalphamonosulphonic acid. (Antiseptic.)
Asbolin. An alcoholic distillate of soot.
Aseptol. Sozolic acid. Orthophenylsulphonic acid (33 per cent aqueous solution).
Astral Oil. Kerosene.
Ater (Atra). Black (Niger).
Atramentum. Black ink.
Indicum (Sinense). India ink.
Auramin. Yellow pyoktanin. (Antiseptic.)
Aureoline. Hair bleach. (A more or less diluted solution of hydrogen peroxide.)
Aurum Musivum (Mosaic Gold). Tin bisulphide.
Axungia. Adeps. (Fat.)
Azurite. Native copper carbonate.

B.

Baker's Ammonia. Ammonium subcarbonate.
Balata. A caoutchouc-like product resembling chicle.
Baldwin's Phosphorus. Calcium nitrate which when heated and exposed to sunlight becomes luminous in the dark.
Balsam, Hungarian. Exudation from Pinus pumilio.
Riga. By distillation from the leaves of *Pinus Cembra.* A thin fluid; odor resembling juniper; properties similar to turpentine.
Sulphur. Sulphurated linseed oil.
Balsamum Arcæi. An ointment of elemi.
Gileadense. Balm of Gilead.
Judaicum. Balm of Gilead.
Nucistæ. An ointment containing the volatile and fixed oils of nutmeg.
Ophthalmicum Rubrum. Ointment of red precipitate.
Saponaceum. Opodeldoc.
St. Yves. Ointment of red precipitate.
Traumaticum. Compound decoction of aloes—also applied to compound tincture of benzoin.
Universale. Ointment of lead subacetate, made with yellow wax and rapeseed oil.
Verum. Balm of Gilead.
Vitæ Hoffmanni. Alcoholic solution of sundry balsamic oils.
Banks Oil. Cod liver oil.
Bannal. Scoparius.
Bardana. Burdock (Lappa).
Barbotine. See Semen Contra.
Barm. Yeast.
Basofor. A trade name for barium sulphate.
Baudruche. Goldbeaters' skin.
Baume de Vie. Compound decoction of aloes.
Bay Salt. Sea salt.
Bell Metal. An alloy of copper and tin.
Bengal Isinglass. Agar.
Benzoic Ether. Ethyl benzoate.
Benzonaphthol. Betanaphthylbenzoate. Betanaphthol-benzoate. (Intestinal antiseptic.)
Benzophenoneid. Apyonin (yellow pyoktanin).
Benzosol. Benzoyl-guaiacol. Guaiacol benzoate (Antitubercular).
Berlin Blue. Prussian blue.
Betel Nut. Areca nut.
Betol. Betanaphthyl salicylate. Betanaphthol salicylate. (Intestinal antiseptic.)
Bhang. Cannabis.
Bicalcic Phosphate. Calcium phosphate dibasic.
Bilis Bovinum. Ox gall.
Bi-Palatinoid. Gelatin capsule divided by a partition, to keep two powders separate until swallowed.
Bitter Chips. Quassia.
Earth. Magnesia.
Root. Gentian.
Salts. Epsom salt.
Sticks. Chirata.
Wood. Quassia.
Bitumen Judaicum. Asphaltum.
Black Balsam. Peru balsam.
Draught. A compound infusion of senna; must not be confounded with "Black Drop".
Drop. Vinegar of opium.
Flux. A mixture of charcoal and potassium carbonate.
Blancard's Pills. Pills of ferrous iodide.
Blanc Fixe. Artificial barium carbonate or sulphate.
de Troyes. Prepared chalk.
Blankit. A proprietary name of a bleaching compound composed of sodium formaldehyde sulphoxylate.
Blue, Berlin. Prussian blue.
Black. A name for ivory-black.
Chinese. Prussian blue.
Copperas. Copper sulphate.
Bluestone. Copper sulphate.
Bolus Alba. Kaolin.
Armenia. Armenian bole.
Bone Ash. Crude calcium phosphate.
Char. Animal charcoal.
Borax, Red. Red oxide of mercury.
Bran Oil. Furfural.
Brass, An alloy of copper and zinc.
Brassil. Pyrites.
Brasium. Malt.
Brazilian Cacao. Guarana.
Brazil Wax. Carnauba wax.
Bromol. Tribromophenol. (Antiseptic.)
Brucite. Magnesium hydroxide.
Butter Color. Annatto.
of Antimony. Solution of antimony chloride.
of Tin. Stannous chloride.
of Zinc. Zinc chloride.
Butylhypnal. Butylchloral-antipyrin.
Butyrum Majoranæ. Ointment of sweet marjoram.
Nucistæ. Expressed oil of nutmeg.

Byne (Bynin). Apparently a favorite name in England for malt and malted preparations.

C.

Caffa. Camphor.
Calcined Plaster. Plaster of Paris.
Calcitea (calcitrea). Sulphuric acid.
Calcithos. Copper subacetate.
Calcium Phosphide. Phetophor.
Calomelanos. Calomel.
Calx Bismuthi. Bismuth subnitrate.
Viva. Quicklime.
Camphor Julep. Camphor mixture.
Tonka Bean. Coumarin.
Canadol. Petroleum ether.
Cancrorum Lapilli. Crabs' stones.
Chelæ. Crabs' claws.
Candelæ Fumales. Fumigating pastilles.
Capita Papaveris. Poppy-heads.
Carbon Black. The soot of natural gas.
Carborundum. Artificial silicon carbide, an abrasive.
Cashoo. Extract of cutch.
Cassius's Purple. A compound of tin with gold oxide.
Celanese. Cellulose acetate.
Cera Sigillata. Sealing wax.
Cerate, Compound Camphor. Camphor ice.
Ceratum Citrini (P. L. 1745). Resin cerate.
Epuloticum (P. L. 1745). Ceratum calaminaris. Turner's cerate.
Galeni. Cold cream.
Labiale. Lip salve.
Lithargyri Acetati Compositum. Goulard's cerate. (P. L. 1787.)
Ceruse. Lead carbonate.
Ceresin. Earth-wax. An impure paraffin.
Cerussa Acetata. Acetate of lead.
Chalcanthum. Copperas.
Charlton White. Lithopone.
Charpie. Lint.
Chelen (Kelene). Ethyl chloride. (Local anesthetic.)
Chemick. A cold dilute solution of chlorinated lime (in textile industry).
China Oil. Balsam Peru.
Chinese Blue. Prussian blue.
Red. Vermilion.
White. Zinc oxide.
Chinium. Quinine.
Chloral Carmine. Staining fluid. Heat 0.05 Gm. carmine, 20 cc. dehydrated alcohol and 30 drops HCl (sp. gr. 1.124) for half an hour on water bath, add 25 Gm. hydrated chloral, and filter.
Choke-damp. A mixture of CO_2 and CO in mines.
Chrome Yellow. Lead chromate.
Chrysotile. Fibrous serpentine—a variety of asbestos.
Christia. Manila paper made waterproof with chrome gelatin.
Chymosin. Pepsin.
Cibus Deorum. Asafetida.
Cina Flores. Santonica.
Cineres Clavellati. Crude potassium carbonate.
Cinnabar (Vermilion). Mercuric sulphide.
Coal-Tar Naphtha. Benzol.
Codoil. Rosin oil.
Coffee, Soudan. Kola.
Cognac. Brandy.
Colcothar. Crude ferric oxide.
Colla Piscium. Isinglass.
Comitissæ Palmæ Pulvis. Magnesium carbonate.
Collaurin. Colloidal gold.
Conchinine (of the German chemists). Quinidine.
Condy's Fluid. A solution of potassium permanganate similar to Liquor Potassii Permanganas B. P., containing 1 per cent of the salt in aqueous solution.
Confectio Cardiaca. Aromatic chalk powder.
Damocratis. *Damocrates' confection.* An aromatic astringent confection containing opium. Originally it contained 64 ingredients.
Connecticut Lead. Barytes.
Constant White. Barium sulphate.
Copra. The dried meat of the coconut.
Corn Sugar. Dextrose.
Cornu Cervi. Hartshorn. Ammonium carbonate.
Cervi Ustum Nigrum. Bone-black.
Cremor Tartari. Cream of Tartar.
Crocus Martis. Ferric oxide.
Metallorum (Antimonii). Brown antimony oxide.
Saturni. Red lead.
Crow Fig. Nux vomica.
Cryst Alba. Refined naphthalene. (Disinfectant.)
Crystalli Tartari. Cream of tartar.
Crystallose. Soluble saccharin.
Crystals of Venus. Cupric acetate.
Cuca. Coca.
Cullet. Broken glass for remelting.
Cuprum Scoriatum. Crude copper acetate. (Verdigris.)
Cutch. Dark (black) gum catechu.
Cyanegg. A proprietary form of egg-shaped lumps of sodium cyanide.
Cyanfran. A proprietary form of granular sodium cyanide.
Cynosbatæ. See Hips.

D.

Dactyli. Dates.
Dagutt. See Daggett, Oil of.
Decoctum Album. A kind of chalk mixture.
Diaphoreticum. Compound decoction of guaiacum.
Lignorum. Compound decoction of guaiacum wood.
Zitmanni. Compound decoction of sarsaparilla.
Degras. Crude wool fat.
Denver Mud. Cataplasm of kaolin.
Derosne's Salt. Narcotine.

Diabolus Metallorum. Tin.
Diacodium. Poppy-heads. (Old name for syrup of poppies.)
Diagrydium. Scammony.
Diana. Silver.
Diapente. A tonic powder, or electuary, composed of 5 ingredients.
Dilapsus. As an adjective to several salts means effloresced.
Dioxytoluene. Orcin.
Dipterix. Tonka bean.
Draco Mitigatus. Calomel.
Drumstick. Cassia fistula.
Dulcin. A new sweetening agent. Paraphenetolcarbamid. (Sucrol.)
Dutch Drops. Haarlem oil.
Liquid. Oil. The chloride of olefiant gas.
Dutch Metal. A cheap imitation of gold leaf made of copper and zinc.
Tea. A variety of St. Germain tea. (Laurent.)
White. White lead.

E.

Earth, Japan. Catechu.
Nut. Peanut.
Wax. Ceresine.
Eau de Broccherai. Creosote.
Luce. Aromatic spirit of ammonia.
Rabel. See Elixir, Haller's.
Ebur Ustum. Bone-black.
Egyptian Privet. Henna.
Eikonogen. Sodium salt of the amidobetanaphtholbetamonosulphonic acid. (For photographic purposes.)
Electrolon. Artificial silicon carbide, an abrasive.
Electrum. Amber. Also applied to a natural alloy of gold and silver—containing approximately 40 per cent of silver.
Electuarium. Confection. (Soft.)
Dentifricium. Tooth paste.
Elephant Louse. The nut of cashew.
Elixir Adjuvans. The U. S. P. elixir of glycyrrhiza.
Anisi. Aniseed cordial.
Aperitivum. Compound tincture of aloes.
Aurantiorum Compositum. A compound elixir of orange peel and gentian.
Corrigens. Aromatic elixir of yerba santa.
Daffy's. Compound tincture of senna.
Garus. Mixture of syrup with an alcoholic distillate of aloes and spices.
Haller's. 3 parts alcohol and 1 part sulphuric acid, mixed slowly.
of Long Life. A modification of the well-known Swedish Bitters.
ad Longam Vitam. Elixir of Long Life.
Pectorale. Compound ammoniated elixir of liquorice with oils of fennel and anise.

Elixir Proprietatis (Paracelsi). Compound tincture of aloes and myrrh.
Purgans. Compound tincture of jalap.
Rhei Darelii. Tinctura rhei dulcis.
Roborans Whyttii. Compound tincture of cinchona (containing safron).
Salutis. Compound tincture of senna.
Stomachic. Stoughton's. Compound tincture of gentian.
Viscerale. Compound tincture of orange peel and gentian.
Vitrioli Mynsichti. Aromatic sulphuric acid.
Emerald green. Copper acetoarsenite, or copper arsenite.
Emplastrum Cantharidum Perpetuum. A mild cantharidal plaster.
Fuscum. Mother plaster. Universal plaster. Brown salve.
Gummosum. Compound plaster of galbanum.
Emulsio Communis. Mistura amygdalæ.
English White. Calcium carbonate.
Ens Martis. Ammoniated iron.
Essence (French). Volatile oil.
of Mirbane. Nitrobenzol. (Artificial oil of bitter almonds.)
of Vinegar. Concentrated acetic acid.
Essentia Bina. Caramel.
Ether, Pyroacetic. Acetone.
Éthérolat, Éthérolaturé, Éthérolé (French). Correspond to the alcoholic terms. (See Alcoolat, etc.)
Eucasin. A compound of casein and ammonia.
Exalgin. Methylacetanilid. Methylphenylacetamide. (Anodyne.)
Expectorant, Stokes'. Senega and squill cough mixture with ammonium carbonate.
Extractum Catholicum. Compound extract of rhubarb.
Martis Pomatum. Crude iron malate in the form of extract.
Panchymagogum Crollii. Compound extract of rhubarb. (Rhubarb, aloes, jalap, soap.)
Eyestones. Crabs' eyes.

F.

Faba Porcina. Suilla. The fruit of Hyoscyamus niger.
Purgatrix. Castor oil bean.
Fæcula. Starch. (Amylum).
Farina Hordei Præparata. Barley flour heated in a steam bath for about thirty hours.
Ferri Scobs. Iron filings.
Ferro Pagliari. Solution of ferrous chloride.
Silicon. An alloy of iron and silica used in metallurgy.
Ferrugo. Iron rust.
Ferrum Alcoholisatum. Finely powdered iron, which is not the same as reduced iron.
Limatum. Iron filings.

Ferrum Pomatum (extract, tincture, etc.). Iron malate.
Fire-damp. Methane.
Fixed Air. Carbon dioxide.
Flake Lead. Lead carbonate.
White. Carbonate of lead.
Flea Seeds. Seeds of Nigella.
Wort. Psyllium seeds, used in chronic constipation.
Florence Oil. Olive oil.
Flores Antimonii. Antimony sesquioxide.
Benzoes. Benzoic acid.
Bismuthi. Bismuth oxide.
Martis. Ferric chloride.
Zinci. Zinc oxide.
Flos Æruginis. Copper acetate.
Salis. Sodium subcarbonate.
Flowers of Antimony. Oxide of antimony.
of Benjamin. Benzoic acid.
of Zinc. Oxide of zinc.
Fluorol. Sodium fluoride.
Fluor Spar. Calcium fluoride.
Flystone. A mixture of cobalt and arsenic.
Fool's Gold. Pyrites.
Formol. Formaldehyde.
Formylum Chloratum. Chloroform.
Fossil Alkali. Sodium Carbonate.
Flour. Kieselguhr.
Wax. Ozokerite.
Fossiline. Similar to petrolatum, vaseline, etc. Vaseline.
Frankincense. Olibanum.
Fraude Reagent. Acid perchloric.
Freezing Salt. Calcium chloride.
Freezine. A name applied to formaldehyde illegally used as a milk preservative.
French Polish. An alcoholic solution of shellac.
White. Pulverized talc.
Fuligokali. An alkaline solution of soot evaporated to dryness.
Fructose. Levulose.
Fruit Sugar. Levulose.
Furol. Furfuraldehyde (Furfural).
Furfur. Bran.
Fustic, Old. The wood of Morus tinctoria.
Young. The wood of Rhus cotinus.

G.

Galactic. Lactic.
Galena. Lead sulphide.
Gallacetophenone. Methylketotrioxybenzol. Methylketotrioxybenzene. Trioxyacetophenone. Alizarin-yellow "C".
Gallein. Coal-tar color. Used as an indicator.
Gallipoli. An impure olive oil used in the textile industries.
Gallobromol. Dibromogallic acid.
Gamene. Madder.
Gannal's Solution. Solution of aluminum acetate.
Garantose. Saccharin.
Gas Black. Lampblack.
Gentian, White. A German rural domestic medicine, which is dried white dog-dung.
German Silver. An alloy of zinc, nickel and copper.
Germantown Black. Lampblack.
Glacies. Ice.
Mariæ. Isinglass-stone; Muscovy glass. (A variety of calcium sulphate.)
Glandes Quercus (Tostæ). Acorns. (Acorn coffee.)
Glass Gall. The scum forming on the surface of melting glass.
of Antimony. Vitrified antimony oxide.
Globuli Martiales. A crude iron tartrate in the form of balls or marbles.
Glutol. Formaldehyde gelatin.
Glycerolé (French). Liquid glycerin preparations.
Glyceryl Borate. Boroglyceride.
Gommeline. Crude dextrin.
Grains d'Avignon. French berries (Rhamnus infectorius).
Grains of Paradise. The pungent seed of Amomum melegueta.
Griffith's White. Lithopone.
Guano. The dried excrement of sea fowl.
Guaza. Cannabis.
Guhr. Kieselguhr.
Guinea Grains. Grains of Paradise.
Gum Barbary, Brown. Acacia.
Benjamin. Benzoin.
Dragon. Tragacanth.
Thus. Frankincense. Sometimes applied to turpentine oleoresin.
Gummi Elasticum. India rubber.
Guttæ (Gutti). Gamboge.
Rubrum Gambiense. Kino.
Scorpionis. } Gum arabic.
Thebaicum. }
Gunjah. Cannabis Indica.
Guru. Kola.
Gypsum. Plaster of Paris.

H.

Hæmatite. Iron ore, bloodstone.
Halite. Rock salt. Sodium Chloride.
Halowax. A proprietary name for a non-inflammable chlorinated naphthalene.
Hamburg Drops. A kind of "Swedish Bitters".
Tea. Identical with St. Germain tea, differently flavored.
Harmaline. Fuchsine.
Hayo. Coca leaves.
Helcosal. Bismuth pyrogallate.
Hepar. Liver (of sulphur, antimony, lime, etc.).
Antimonii. An impure antimonium and potassium sulphide.
Calcis. Calcium sulphide.
Sulphuris. Potassa sulphurata. "Liver of sulphur".
Hickery-Pickery. Powder of aloes and canella.
Hicra Picra. Same as Hiera Picra.
Hips. The fruit of dog-rose.
Holywood. Guaiacum.

Homberg's Phosphorus. Calcium chloride which when fused and exposed to the sun, becomes phosphorescent in the dark.
Pyrophorus. A mixture of alum and brown sugar, or of potassium sulphide, alumina, and charcoal.
Honey Sugar. Dextrose (misnamed as honey is principally levulose).
Horse Salt. Glauber's salt.
Huxham's Tincture of Bark. Compound tincture of cinchona.
Hydracetine. Acetophenylhydrazine. Pyrodine. Acetylphenylhydrazine.
Hydrargyri Oxymurias. Corrosive chloride of mercury.
Hydrargyrus Calcinatus. Red mercuric oxide.
Muriatus. Corrosive chloride of mercury.
Hydrochrite. Barley water.
Hydrolat (French). A distilled water.
Hydrolé (French). An aqueous solution.
Hydropege. Spring or hydrant water.
Hydrophilous (Hygrophilous) Cotton. Absorbent cotton.
Hypnal. Chloral-antipyrin. Trichloraldehydphenyldimethylpyrazolone. (Hypnotic.)

I.

Ibit. Bismuth oxyiodo tannate.
Ichthyocolla. Isinglass.
Imperial Green. Copper acetoarsenite.
Indian Pink. Spigelia marilandica.
Indicum. Indigo.
Inflammable Air. Hydrogen.
Invar. Ferro-nickel alloy.
Iodo Hydromal. Thymol Iodide.
Iodosol. Thymol Iodide.
Iodothymol. Thymol Iodide.
Iodopyrin. Iodoantipyrin. Antipyrin monoiodide.
Ipado. Coca leaves.
Iron Pyrolignite. Crude ferric acetate liquor used in mordanting.
Issue Peas. Small orange berries, or round pills turned from orris root.
Itrol. Silver citrate.

J.

Jaggery. Crude or raw sugar from the date palm.
Japan Earth. Catechu.
Java Pepper. Cubeb.
Jesuits' Balsam. Copaiba.
Bark. Cinchona.
Drops. Contain guaiacum, sarsaparilla, and Peruvian balsam, also a synonym for compound tincture of benzoin.
Jewelers' Rouge. Ferric oxide made by igniting iron oxalate.
Jews' Pitch. Asphaltum.
Judas's Ear. A fungus of elder-tree. (Exidia.)
Jupiter. An ancient name for tin.
Jusculum. Broth (of beef, veal, turtle, etc.).

K.

Kali Aeratum. Potassium carbonate.
Kalicum Hydras. Fused potassa.
Kefir. A kind of kumyss.
Kelene. Chelen. Ethyl chloride.
Ketopropane. Acetone.
King's Yellow. Yellow arsenic sulphide.
Knock-out-drops. Chloral hydrate.

L.

Lac Magnesiæ. Milk of magnesia.
Virginis. See Virgin's Milk.
Lacca Cœrulea. Litmus.
Musica (Lakmus). Litmus.
Lactin. Sugar of milk.
Lady's Blush. Carmine.
Lamotte's Drops. Ethereal tincture of ferric chloride.
Lanain. Adeps lanæ. Lanolin.
Lanalin. Lanolin.
Lanesin. Lanolin.
Lanichol. Lanolin.
Laniol. Lanolin.
Lana Philosophica. Zinc oxide.
Lapides Cancrorum. Eyestones.
Lapilli Cancrorum. Crab's eyes, crab stones; concretions found in the stomach of the European crawfish.
Lapis Amianthus. Asbestos.
Baptista. Ancient name for talcum.
Calaminaris. Impure zinc carbonate.
Causticus. Potassa. (In sticks.)
Cœruleus. Copper sulphate.
Divinus. Copper aluminate.
Hæmatites. Bloodstone.
Infernalis. Lunar caustic. (Fused silver nitrate.)
Alkalinus. Caustic potash.
Lazuli. Ultramarine.
Ophthalmicus. Eyestones.
Smiridis. Emery.
Lead Flake. Lead carbonate.
Leiocom. Dextrin.
Leipzig Yellow. Lead chromate.
Lenitive Electuary. Confection of senna.
Leucœnus. White wine.
Leucogene. Sodium bisulphite.
Levant Nut. Cocculus Indicus. (Fish berries.)
Lichen Islandicus. Iceland moss.
Life-Everlasting. Gnaphalium polycephalum.
Lignia Nitrica. Gun-cotton.
Lignum Sanctum. Guaiacum wood.
Vitæ. Guaiacum wood.
Lilacine. Terpineol.
Limatura Ferri. Iron filings.
Liquor Anodynus (Hoffmanni). Hoffmann's anodyne.
Cornu Cervi (Liquor C.C.). Solution of ammonium carbonate, containing empyreumatic oil.

Liquor Cornu Cervi Succinatus (Liquor C.C. Succinatus). Solution of ammonium succinate.
Electropœicus. Battery fluid consisting of sulphuric acid and potassium dichromate.
Ferri Oxychlorati. Dialyzed iron.
Fumans Boylii. Ammonium hydrosulphide.
Seriparus. Liquid rennet.
Stypticus Loofii. Solution of ferric chloride.
Lithopone. A pigment consisting of a mixture of barium sulphate, zinc sulphide, and zinc oxide.
Lixivium Saponarium. Liquor potassii hydroxidi.
London Paste. Soda with lime.
Looch Album. An emulsion of almonds and oil of almonds.
Loofah. "Vegetable sponge"; the skeleton of a gourd.
Love-Apple. Tomato.
Luna. Silver.
Lustron. Cellulose acetate.

M.

Magisterium Bismuthi. Bismuth subnitrate.
Coccionellæ. Carmine.
Sulphuris. Washed sulphur.
Magnalium. An alloy of aluminum and magnesium.
Magnesia Alba. Magnesium carbonate.
Nigra. Black manganese oxide.
Mala. Poma (apple).
Manna Metallorum. Calomel.
Manganese, Battery. Manganese dioxide.
Manganin. An alloy principally consisting of copper and manganese.
Marcasit. Metallic bismuth also applied to a form of iron pyrites.
Marine Acid. Hydrochloric acid.
Salt. Sodium chloride, sea salt.
Mars, or Martis. Iron (Tinctura Martis is tincture of iron).
Massicot. Lead protoxide.
Mater Metallorum. Mercury.
Matta. The cortical portion from a variety of millet-seed, used for adulterating pepper.
Maw-Seed. Poppy-seed.
Meadow Saffron. Colchicum.
Meconium. The juice of the poppy.
Medulla Bovis. Ox-marrow.
Lactis. Butter.
Sassafras. Sassafras pith.
Mel Ægyptiacum. Liniment of copper.
Melagueta Pepper. Grains of Paradise.
Meleguette Pepper. Grains of Paradise.
Melanosmegma. Soft (green) soap.
Mephite of Soda. Impure sodium carbonate.
Mercurius Dulcis. Calomel.
Præcipitatus Albus. A name for calomel.
Mortis. / **Vitæ.** } Antimony oxide.
Mercury, Hahnemann's Soluble. Black mercury oxide.
Chloramide. Ammoniated mercury.
Coagulated. Red oxide of mercury.
Metal, Fusible. An alloy melting below 100° C. used in safety sprinklers, fusible plugs and castings of perishable objects. Usually consisting of lead, tin and bismuth.
Monel. An alloy of nickel, copper, cobalt and iron.
Methacetine. Paraacetanisidine. Paraoxymethylacetanilid. Acetylmethylparamidophenol. (Antipyretic.)
Methanilid. Exalgin.
Metheglin. Honey wine. Mead.
Methonal. Dimethylsulphonedimethylmethane.
Methylacetal. Acetone.
Methyl Benzol. Toluol.
Theobromine. Caffeine.
Metol. Salt of monomethylparaamidometacresol (for photographic uses).
Metopium. Expressed oil of almonds.
Metozin. Antipyrin.
Metpozin. Antipyrin.
Metrenchyta. Vaginal injection; sometimes a vaginal syringe.
Mica Panis. Bread crumb.
Microcidin. Sodium betanaphthol. Sodium betanaphtholate (75 per cent). (Antiseptic.)
Microcosmic Salt. A mixture of sodium and ammonium phosphates.
Mikozone. Hypnotic and sedative. (A variety of chlorodyne.)
Milk of Sulphur. Precipitated sulphur. (Strictly only that precipitated by sulphuric acid.)
Virgin's. Rose water rendered milky by the addition of tincture of benzoin.
Mineral Gum. Soluble glass; sodium or potassium silicate.
Mineral Wax. Ceresin or ozokerite.
Wool. Asbestos. Also applied to an artificial product made from slag or lava spun into fine threads.
Minium. Red lead.
Græcorum, Minium Purum. Red mercuric sulphide.
Mirabilite. A naturally occurring form of crude Glauber's salt.
Miraculum Chemicum. Magnesium carbonate.
Mithridate. See Confectio Damocratis.
Mistura Acaciæ. Mucilage of gum arabic of variable strength.
Oleoso-Balsamica. An alcoholic solution of Peru balsam, oil of amber, and sundry volatile oils.
Mixtura Alba. Compound chalk mixture.
Salina. Potio Riveri. (Effervescent mixture of potassium citrate.)
Solvens. Solution of ammonium chloride with liquorice.

Mixtura Solvens Stibiata. Solution of ammonium chloride with liquorice and tartar emetic.
Mixture, Antidysenteric. Acid camphor mixture.
Dysmenorrhœa. Guaiac mixture with corrosive sublimate.
Mohr's Salt. Ferrous ammonium sulphate.
Mollin. A proprietary name for a potash coconut oil soap.
Molybdos. Lead.
Monel Metal. A non-corroding alloy of nickel, copper, cobalt and iron.
Montau Wax. A waxy substance obtained from European lignite.
Mosaic Gold. Tin bisulphide.
Mountain Fat. Paraffin.
Muride. } Bromine.
Murina. }
Muscus. Moss. (Iceland, Irish, etc.).

N.

Nægelis Solution. Solution of zinc chloro-iodide.
Naphæ Flores (Aqua). Orange flowers (water, etc.).
Naphtha. A volatile solvent.
Coal Tar. Benzene C_6H_6.
Petroleum. Benzin.
Vitrioli. Ether.
Naphthalol. Betol.
Naphthosalol. Betol.
Naphthyl. Naphthol.
Natrium Sodium Natron. Sodium carbonate.
Natro-Kali Tartaricum. Rochelle salt.
Neapolitan Ointment. Mercurial ointment.
Neogale. Fresh milk.
Nichrome. A nickel-chromium alloy.
Nico. Nickel carbonmonoxide.
Nigramentum. Black ink.
Nigrosine. A member of a class of blue or black dyestuffs of coal-tar origin.
Nihil Album. Crude zinc oxide.
Griseum. Zinc oxide.
Nitratine. Sodium nitrate.
Nitre Cake. Acid sodium sulphate.
Rough. Magnesium chloride.
Nitrum Flammans. Ammonium nitrate.
Saturninum. Lead nitrate.
Nix Zinci. Zinc oxide.
Norit. A proprietary name for a form of animal charcoal used in decolorizing.
Nulomoline. A proprietary form of invert sugar.
Number Six. Tincture of capsicum and myrrh. (Hot drops.)
Nux Aromatica. Nutmeg.
Metella. Nux vomica.
Moschata. Nutmeg.
Nucista. Nutmeg.

O.

Ocher or Ochre. An earthy iron oxide, yellow, red or brown, used as a pigment.
Œnanthic Ether. Artificial oil of cognac.
Œsipus. Suint. Impure wool fat.
Oil, "American". Scandinavian for castor oil.
Animal. See Dippel's oil.
Astral. Kerosene.
Banana. Amyl acetate.
of Bay. Oil of laurel berries. (Generally is understood to mean oil of bay rum.)
of Ben (or Behen). Comes from a Moringa, and is not the same as oil of benne, which comes from a Sesamum.
Bone. See Dippel's oil.
of Cassia, Artificial. Cinnamic aldehyde is sometimes sold under this title.
Colza. Oil of rapeseed.
Copra. Coconut oil.
Crude. Petroleum.
Dagget. Empyreumatic oil of birch. (Oil of Russia leather.)
Dippel's. Also called *Dippel's animal oil*, an evil smelling distillate from bones or other animal matter.
of Eggs. By expression from hard-boiled yolks.
Grain. Amyl alcohol.
Hardened. Hydrogenated oils.
of Niobe. Methyl benzoate.
Rock. Petroleum.
Seneka. Crude petroleum.
of Smoke. Creosote.
Sod. Crude wool fat.
Solar. Kerosene.
Swallow. Infused oil of elder flowers.
Sweet. Olive oil.
of Tartar. Solution of potassium carbonate.
Ointment, Black Basilicon. Basilicon ointment with pitch.
Maury's. A compound rhubarb ointment.
Neapolitan. Mercurial ointment.
Troopers'. Mercurial ointment.
Volatile. Volatile liniment.
Oleite. Sodium sulphoricinoleate.
Oleum Animale Fœtidum. Crude oil of hartshorn. Dippel's animal oil.
Anthos. Oil of rosemary.
Betulinum. Empyreumatic oil of birch. (Oil of Russia leather.)
Bubulum. Neatsfoot oil.
Cedræ (de Cedro). Oil of lemon.
Chaberti. Rectified animal oil.
Chamomillæ Citratum. Oil of lemon, distilled over German chamomile.
Cocois. Oil of coconut.
Coctum. Fixed oil (olive oil) infused with the respective herb, etc.
Cornu Cervi (Fœtidum). Crude animal oil.
Fermentationis. Fusel oil.
Juniperi Oxycedri (Empyreumaticum). Oil of cade.
Laurinum. Expressed oil of laurel berries.

Oleum Lumbricorum. Infused oil of earthworms.
Napi. Rapeseed oil.
Nervinum. Neatsfoot oil.
Nucis Moschatæ. Besides the two kinds of oils (volatile and fixed) see also Balsam Nucistæ.
Nucistæ. Expressed or volatile oil of nutmeg.
Omphacinum. Crude olive oil.
Palmæ Christi. Castor oil.
Pear. Amylacetate.
Petræ. Crude petroleum. (Seneka oil.)
Philosophorum. Olive oil distilled over hot bricks.
Portugallicum. Oil of bergamot.
Rusci. Empyreumatic oil of birch. (Oil of Russia leather.)
Tartari per Deliquium. Concentrated solution of potassium carbonate.
Templinum. Oil of pine cones and small branches of Pinus pumilio.
Terræ. Crude petroleum.
Omal. Trichlorphenol.
Opodeldoc, Steers's. Solid opodeldoc.
Orellana. Annatto.
Orleana. Annatto.
Orr's White. Lithopone.
Oryza. Rice.
Os Sepiæ. Cuttlefish bone.
Oxalium. Potassium binoxalate.
Oxy-di-methyl-chinizin. Antipyrin.
Oxymel Æruginis. Honey with copper acetate.
Oxone. Sodium peroxide.
Ozokerite. Earth-wax; an impure paraffin.

P.

Pack Tong. German silver.
Palacetyrus. Old cheese.
Palsy Drops. Compound tincture of lavender.
Panacea Mercurialis. Calomel.
Panchymagogum Minerale (P. Quercetani). Calomel.
Paraffin Scale. Paraffin.
Paris Black. Animal charcoal.
Green. Copper arsenoacetate.
Yellow. Lead chromate.
White. Calcium carbonate.
Parkesine. Celluloid.
Parodyne. Antipyrin.
Passulæ. Raisins.
Minores. Corinthian raisins. (Grocers' "currants".)
Pearlash. Crude potassium carbonate.
Pearl Moss. Chondrus.
White. Bismuth subnitrate, also bismuth subcarbonate.
Pear Oil. Amyl acetate.
Pental. Trimethylethylene. Betaisoamylene. (Anesthetic.)
Pepperette. Olive pits. (For adulterating pepper.)
Perborin. Sodium perborate.
Permanent White. Barium sulphate.
Permutit. An artificial zeolite used for water softening and purification.
Petrol. Gasoline. Motor fuel.
Petrolene. Asphalt.
Pewter. An alloy of tin and antimony.
Phalaris. Canary seed.
Phenates. Carbolates.
Phenetol. Ethyl phenate.
Phenic Acid. Carbolic acid.
Phenocoll. Amidoacetoparaphenetidine. Glycocoll-paraphenetidine. (Antipyretic.)
Phenolin. Mixture of soap with cresols.
Phenylic Acid. Carbolic acid.
Phenylone. Antipyrin.
Phosgene. Carbonyl chloride.
Photophor. Calcium phosphide.
Photoxylin. Similar to gun-cotton, but made from wood-pulp.
Phyllis Amara. Bitter almond bran.
Pills, Eternal. Pills of metallic antimony, about 15 grains each, which, after use, were recovered from the stools and washed.
Perpetual. See Pills, Eternal.
Pinguedo. Lard.
Pinguoleum. Fixed oil.
Pink Salt. Stannic chloride.
Piperonal. Heliotropin.
Pisselæum Indicum. Petroleum.
Plasma. Glycerite of starch.
Plaster, Diachylon. Lead plaster.
Nuremberg. Brown plaster. Mother plaster.
Plumbago. Black lead. Also a genus of herbs.
Plumbum Album. Tin.
Scytodepsicum. Moist lead tannate.
Plutonium. Barium.
Poison Nut. Nux vomica.
Parsley. Conium.
Tobacco. Hyoscyamus.
Poivrette. Olive pits; adulterant of pepper.
Poma Aurantii (-iorum). Orange buds.
Pompholix. Zinc oxide.
Potassium Chromate (neutral). Yellow potassium chromate.
Hydriodate. Potassium iodide. (Kalium hydro-iodicum of German prescriptions.)
Hyperoxymuriate. Potassium chlorate.
Rhodanate. Potassium sulphocyanide (-cyanate).
Potato Spirit. Fusel oil.
Potstone. Talc.
Potpourri. Fumigating species, chiefly flowers, generally preserved with salt.
Powder, Digestive. Compound powder of pepsin.
of Algaroth. Antimony oxide.
Précipité Blanc (French). This, in French prescriptions, for internal use, is calomel (by the wet process), and for external use it generally means white precipitate.
Preparing Salt. Sodium stannate.

Preservaline. A proprietary name applied to a line of food preservatives consisting of formaldehyde, sulphites, borax, etc., all of which are illegal.
Preston's Salts. Ammonium carbonate.
Propanone. Acetone.
Propenal. Acrolein.
Prussian Blue. Ferric ferrocyanide.
Pudding Pipe. Cassia fistula.
Stick. Cassia fistula.
Pulvis Ærophorus. Effervescing powder. (Soda, Seidlitz.)
Albus Romanus. Magnesium carbonate.
Diatragacanthæ. Starch, liquorice root, gum arabic, and sugar.
Digestivus. Rhubarb, saltpetre, and cream of tartar.
Gummosus. See Pulvis Diatragacanthæ.
Infantum. When for internal use: magnesia and rhubarb, with oil of fennel. When for external use: baby dusting-powder.
Jacobi. Antimonial powder.
Puerorum. See Pulvis Infantum (internal use).
Purple of Cassius. Gold precipitated from solution by tin chloride.
Purple Oxide. Ferric oxide.
Putty. A plastic mixture of whiting and linseed oil used by painters and glaziers.
Powder. Polishing substance. Tin oxide.
Putz Pomade. A polishing ointment, containing ferric oxide, and probably pumice-stone.
Pyracine. Antipyrin.
Pyrene. A fire extinguishing fluid consisting of carbon tetrachloride.
Pyroalcohol. Methyl alcohol.
Pyrodine. Acetophenylhydrazine. Hydracetin. Acetylphenylhydrazine.
Pyrœnus. Alcohol.
Pyrophorus. A mixture of certain substances which ignite spontaneously when exposed to the air.

Q.

Quaker Button. Nux vomica.
Quaker's Black Drop. Vinegar of opium.
Quassation. In pharmacy, the act of reducing roots and tough barks to morsels.
Quickwater. Solution of mercuric nitrate.

R.

Radical Vinegar. Glacial acetic acid.
Radumine. A proprietary name for a synthetic form of oxalic acid.
Raisins, Corinthian. Grocers' currants.
Ramenti Ferri. Iron filings.
Realgar. Red arsenic sulphide.
Red Cerate. Calamine cerate.
Reddle. Red chalk.
Red Liquor. Aluminum acetate solution.
Oil. Crude oleic acid.
Tartar. Argols.
Regulus (Antimonii, etc.). The pure metals, when separated by fusion.
Resina Elastica. India rubber.
Empyreumatica Liquida. Tar.
Empyreumatica Solida. Pitch.
Flava. Rosin. (Colophony.)
Pini. Turpentine (solid, hard).
Retinol. Rosin oil. Rosinol.
Rex Metallorum. Gold.
Rizine. Rice, partially acted upon by superheated steam.
Rob (Roob). Inspissated juice (of elderberries, carrot, juniper berries, etc.).
Rock Crystal. Quartz—SiO_2.
Salt. Native sodium chloride.
Roman Vitriol. Copper sulphate.
Rongalite. A proprietary name for a bleaching compound composed of sodium hydrosulphite.
Rottenstone. Tripoli.
Rose Pink. Whiting colored with decoction of Brazil wood and pearl ash.
Rosinol. Rosin oil.
Rouge. Red ferric oxide.
Rubigo Ferri. Iron-rust.
Rubramentum. Red ink.
Ruddle. A kind of red chalk. Reddle.
Rufus's Pills. Pills of aloes and myrrh.

S.

Sacchari Fœx. Molasses.
Saccharolé (French). Any moist liquid preparation (except syrup) which contains sugar in large proportions.
Saccharum Acerinum. } Maple sugar.
Canadense. }
Candum (Candisatum). Rock candy.
Saturni. Sugar of lead.
Sacred Elixir. Compound tincture of rhubarb.
Saffron, American. Safflower.
Saim. Adeps.
Sal Absinthii. Potassium carbonate.
Acetosellæ. Potassium oxalate. (Generally oxalic acid is expected.)
Æratus. Potassium bicarbonate, usually applied at present to sodium bicarbonate.
Alembroth. A mixture of mercuric and ammonium chlorides.
Amarum. Magnesium sulphate.
Ammoniacum Martiale. Iron ammoniochloride.
Ammoniacum Secretum Glauberi. Ferrous sulphate.
Ammoniacum Volatile. Ammonium carbonate.
Anglicum. Magnesium sulphate.
Antihystericum. Potassium acetate.
Argenti. Silver nitrate.

Sal Armeniacum. Ammonium chloride.
Artis. A mixture of mercuric and ammonium chlorides.
Benjamin. } Benzoic acid.
Benzoin. }
Catharticus Amarus. Magnesium sulphate.
Catharticus Anglicanus. Magnesium sulphate.
Catharticus Glauberi. Sodium sulphate.
Chalybis. Iron sulphate.
Communis. Sodium chloride.
Culinaris. Sodium chloride.
Cornu Cervi. Ammonium subcarbonate.
de Duobus. Potassium sulphate.
Diureticus. Potassium acetate.
Enixum. Potassium bisulphate.
Essentiale Tartari. Tartaric acid.
Febrifugum. Potassium acetate.
Fossilis. Sodium chloride.
Fuliginis. Ammonium carbonate.
Gemmæ. Sodium chloride.
Lactis. Milk sugar.
Magnesia Vitriolata. Magnesium sulphate.
Marinum. Sea salt.
Martis. Ferrous sulphate.
Microcosmicum. Salts of urine.
Mirabile Glauberi. Sodium sulphate.
Nitrum. Potassium nitrate.
Ossium. Ammonium carbonate.
Panchrestum. Potassium tartrate.
Perlatum. Sodium phosphate.
Petræ. Potassium nitrate.
Polychrestum Seignetti. Rochelle salt.
Polychrestus. Potassium sulphate.
Glaseri. Potassæ sulphas cum sulphure.
Prunella. Potassium nitrate fused.
Rupellensis. Rochelle salt.
Sapientiæ. Sal alembroth.
Saturni. Lead acetate.
Scientiæ. Sal alembroth.
Sedativus Hombergi. Boracic acid.
Sedlicensis. Magnesium Sulphate.
Sennerti. Potassium acetate.
Seydschutzense. Magnesium sulphate.
Soda. Ordinary crystallized washing soda or sodium carbonate.
Succini. Succinic acid.
Tartari. Potassium carbonate.
Essentiale. Tartaric acid.
Thermarum (Carolinarum). Carlsbad salt.
Urinæ. Sodium phosphate.
Vegetabile. Potassium tartrate.
Vitæ. Sal alembroth.
Vitrioli. Zinc sulphate.
Vitrioli Narcoticum. Boracic acid.
Volatile. Ammonium carbonate.
Volatile Liquid. Ammonia water.
Vomitorium Vitrioli. Zinc sulphate.
Salamander's Blood. Fuming nitric acid.
Salmiac (German). Ammonium chloride.
" Salts ". Usually Epsom salt.
Salt Cake. Crude acid sodium sulphate obtained as a by-product in chemical industries.
Fruit. A variety of Seidlitz (or Seltzer) aperient.
Herapath's. Quinine iodosulphate.
of Mars. Ferrous sulphate.
Microcosmic. Sodium and ammonium phosphate.
Mordant. Tartar emetic.
of Saturn. Lead acetate.
Seignette. Rochelle salt.
Sore-Throat. Sal prunellæ.
of Tartar. Pure potassium carbonate.
of Tin. Tin chloride.
Salzburg Vitriol. Copper sulphate.
Sand Acid. Acid hydrofluosilicic.
Sandiver. See Glass Gall.
Sandyx. Red lead oxide.
Sapo Medicatus. A good quality of neutral white Castile soap.
Satin Spar. Gypsum.
Saturatio. Solution of sodium citrate.
Saturnus (Saturni). Lead.
Saxin. Saccharin.
Schweinfurth's Green. Copper arsenite.
Scotch Soda. Crude sodium carbonate.
Sea-Onion. Squill.
Sebum (Sevum). Suet. Tallow.
Seignette's Salt. Rochelle salt.
Selenite. Gypsum.
Semen Contra. Wormseed from Barbary.
Cynæ. Santonica. Levant worm-seed.
Sanitum. The seed of Artemisia santonica.
Semencina. Levant wormseed. (Santonica.)
Semina Strychni. Nux vomica.
Sepia. Cuttle fish bone.
Sepiolite. Meerschaum.
Sericose. Cellulose acetate.
Serum (Lactis, etc.). Whey (milk, etc.).
Shikimol. Safrol.
Sideros. Iron.
Silex. Quartz.
Siliqua Dulcis. St. John's bread.
Silocel. A proprietary form of kieselguhr used for heat insulation.
Slag Wool. Mineral wool.
Sludge Acid. Spent sulphuric acid in chemical industries.
Smalt. A potash cobalt glass, used as a pigment and in ceramics.
Sod Oil. Degras.
Soilime. A lime containing residue of the cyanimide industry, used in agriculture.
Sol. Gold.
Soluble Glass. Sodium silicate.
Solvin. See Polysolve.
Spanish White. Bismuth subnitrate, also calcium carbonate.
Sparadrap. Spread adhesive plaster
Spadium Stearite. Zinc oxide.
Spathum Fluoricum. Fluor-spar.
Spelter. Zinc.
Speltrum. Zinc.

Sperma Mercurii. Mercury acetate.
Spiegeleisen. Ferromanganese alloy.
Spina Cervina (Baccæ, etc.). Buckthorn berries, etc.
Spirit of Nitre. Crude nitric acid.
Pyro-Acetic. Acetone.
of Salt. Crude muriatic acid.
of Turpentine. Oil of turpentine.
Spiritus. See also Liquor.
Inflammabilis. Alcohol (sometimes whisky).
Juniperi. Generally gin.
Lethalis. Carbonic acid.
Mindereri. Solution of ammonium acetate.
Muriatico-Æthereus Martiatus. Tinctura ferri chloridi ætherea.
Nitri Dulcis. Sweet spirit of nitre.
Duplex.
Fumans.
Glauberi.
} Nitric acid.
Nitrico-Æthereus. Sweet spirit of nitre.
Odoratus. Cologne.
Pyroxylicus. Methylic alcohol.
Sacchari. Rum.
Salis Fumans. Muriatic acid.
Sulphurico-Æthereus. Spirit of ether. (Hoffmann's drops.)
Veneris. Acetic acid.
Vitrioli. Diluted sulphuric acid.
Vitrioli Dulcis. Hoffmann's anodyne.
Spodium. Crude bone charcoal. (Ivory-black.)
Stannum Cinereum.
Glaciale.
} Bismuth.
Indicum. Zinc.
Starch Gum. Dextrin.
Steatite. Talc.
Steel Drops. Tincture ferric chloride.
Mixture. Mistura ferri composita.
Tincture. Tincture ferric chloride.
Stibio-Kali Tartaricum. Tartar emetic.
Stibium. Antimony.
Stipites Dulcamaræ. Dulcamara.
Storax Calamita. Solid storax. (Generally sawdust or residue of cinchona preparations mixed with liquid storax.)
Strike. Ammonia water.
Stypteria. Alum.
Styracol. Guaiacol cinnamate. Cinnamyl-guaiacol. (Antiseptic.)
Styrone. Cinnamyl alcohol.
Succata. "Citron" of the grocers.
Succinum (Oleum, etc.). Amber. (Oil, etc.)
Succolata. Chocolate.
Sucrol. Paraphenetolcarbamide. (Sweetener.)
Sugar Color. Caramel.
Suffitus. Fumigation.
Sugar Sand. Crude milk sugar.
Suint. Œsipus. Impure wool fat. (Antiseptic.)
Sulphas Americanus Australis. Quinine sulphate.
Sulphur Antimoniatum Fuscum. Precipitated sulphuret of antimony.
Auratum. Golden sulphur. (Antimony sulphide.)
Nigrum. Impure native sulphur.
Stibiatum Rubrum (Rubeum). Kermes mineral, antimony, sulphide and oxide.
Vivum. Impure native sulphur.
Sweet Oil. Olive oil.
Syrup, Cuisinier. Compound syrup of sarsaparilla.
Syrupus Balsamicus. Syrup of Tolu.
Communis. Molasses.
Diacodii. Syrup of poppy-heads.
Empyreumaticus. Molasses.
Fuscus. Molasses.
Hollandicus. Molasses.

T.

Tabloids. Trademark applied to compressed and other goods, etc. Burroughs, Wellcome & Co., London.
Tachiol. Silver fluoride.
Tailed Pepper. Cubeb.
Tartarus. Crude potassium bitartrate (argols). Then, several potassium salts.
Boraxatus. Potassium and sodium borotartrate.
Natronatus. Rochelle salt.
Tartarisatus. Potassium tartrate.
Vitriolatus. Potassium sulphate.
Terebinthina Cocta. Turpentine (hard, solid).
Terpilenol. Terpineol.
Terra Alba. Variously applied to barium sulphate, clays and other heavy white mineral products.
Blanche. Whiting. Crude calcium carbonate.
Cariosa. Rottenstone.
Foliata. Sulphur.
Mineralis. Impure sodium carbonate.
Tartari. Potassium acetate.
Fullonica.
Fullonum.
} Fuller's earth.
Japonica. Catechu.
Ponderosa. Natural barium sulphate.
Sigillata (Alba, Rubra). White and red bole.
Thebaicum. Containing opium.
Theriaca. Molasses.
Andromachi. An aromatic astringent confection containing opium, which originally had more than 70 ingredients.
Thermit. A mixture of powdered aluminum and iron oxide used in metallurgy and in incendiary war bombs.
Thiolin. Salts of thiosulphonic acid. Salt of thiolinic acid. Sulphonated and sulphurated linseed oil.
Thomas Balsam. Balsam Tolu.

Thymolol. Thymol iodide.
Tincal. Native borax.
Tinctura Hiera. Wine of aloes.
Japonica. Tincture of catechu.
Melampodii. Tincture of black hellebore.
Stomachica. Compound tincture of cardamom.
Thebaica. Tincture of opium.
Tincture, Antacrid. Guaiac mixture with corrosive sublimate.
Antiperiodic. A kind of Swedish bitters with quinine.
Tonquinol. Trinitroisobutyltoluol. Substitute for musk.
Tous-les-mois. Canna starch.
Traumaticine. Solution of gutta-percha.
Treacle. Originally "Theriac". In English prescriptions it means "molasses".
Venice. See Theriaca Andromachi.
Trifolium Fibrinum. Menyanthes. (Buckbean. Bogbean.)
Trimethylamine. Is not exactly the same as propylamine, though often prescribed thus.
Trip. Iron subcarbonate.
Tripoli. A natural friable siliceous rock used for polishing, not the same as kieselguhr.
Tripolite. Kieselguhr.
Turionis Pini. Pine cones.
Turnsol. Litmus.
"Turps". Oil of turpentine.
Tusche. India ink.
Tushy-Stone. A gray zinc oxide.
Tutenag. Zinc oxide.
Tutia. Impure zinc carbonate or oxide.
Tutty. Impure zinc oxide.

U.

Ultramarine. German blue.
Umber. A brown earthy ferruginous material, used as a pigment, either raw or burnt.
Unction. Mild mercurial ointment.
Unguentum Ægyptiacum. Honey with acetate of copper.
Cerussæ Acetatæ (P. L. 1787). Cerate of lead acetate.
Diapompholygos. Ointment of impure zinc oxide.
Myrrhæ. Ointment basis: 1 part of myrrh and 10 parts of wax melted together with oil.
Nervinum. Compound ointment of rosemary.
Ophthalmicum. A mild ointment of mercuric oxide.
Quercinum. Soft (moist) lead tannate.
Unguentum Scytodepsicum. Moist lead tannate.
Urao. Native hydrous sodium carbonate.

V.

Vandyke Brown. A ferruginous earthy pigment.
Vaporole. Trademark applied usually to capsules containing medicaments for inhalation, etc. Burroughs, Wellcome & Co., London.
Vegetable Gum. Dextrin.
Sulphur. Lycopodium.
Venetian Red. An artificial iron oxide used as a pigment.
Vermilion. Red mercuric sulphide.
Venus. Copper.
Crystals of. Copper acetate.
Vienna Powder. Potassa with lime.
Vinegar Naphtha. Ethylacetate.
Salts. Calcium acetate.
Vinum Adustum. Alcohol. (Sometimes brandy.)
Crematum. Brandy.
Virgin's Milk. A mixture of tincture of benzoin and rose water.
Viride Æris. Verdigris. (Crude copper acetate.)
Viscum Album. Mistletoe.
Vitriolum Cupri. Blue vitriol.
Vitriolum Romanum. Blue vitriol.
Vomiting Salt. Zinc sulphate.

W.

Waterglass. Sodium or potassium silicate.
White Cinnamon. Canella.
Copperas. Sulphate of zinc.
Flake. Lead carbonate.
Lead. Lead carbonate.
Liquor. Southern negro term for alcohol.
"Nix". Crude zinc oxide.
Pearl. Bismuth subnitrate or chloride.
Permanent. Artificial barium carbonate or sulphate.

Y.

Yellow Arsenic. Yellow arsenic sulphide.
Precipitate. Yellow mercuric oxide.

Z.

Zaffre. A pigment similar to smalts.
Zinc White. Zinc oxide.
Zootic Acid. Prussic acid.
Zooticum. As adjective to several salts Hydrocyanate.
Zylonite. Celluloid.
Z. Z. Anciently myrrh, now zingiber, Ginger.

CHAPTER CXXVI

GLOSSARY

OF

MEDICAL TERMS[1]

Abortifacient, *ab-or-te-fa'-shent*—Agents which terminate pregnancy.
Absorbents, *ab-sorb'-ents*—Drugs that absorb moisture, wound secretion, or gas.
Absorption, *ab-sorp'-shun*—The process of taking a drug into the general system.
Acidosis, *as-id-o'-sis*—A diminution of the normal alkali reserve of the body.
Acne, *ak'-ne*—Inflammation of the sebaceous glands from retained secretions (pimples).
Acromegaly, *ak-ro-meg'-al-e*—An abnormal development, chiefly of the bones of the face and extremities.
Agglutinin, *ag-glu'-tin-in*—An antibody which acts on bacteria in such a way as to cause them to come together in masses or clumps.
Albuminuria, *al-bu-min-u'-re-ah*—The presence of albumin in the urine.
Allergy, *al'-er-gy*—An altered reaction. A general term applied to various kinds of protein sensitivity.
Alteratives, *awl'-ter-a-tivs*—Agents which in some way alter the processes of nutrition and excretion and thereby are of benefit in many diseases of a chronic type.
Amenorrhea, *a-men'o-re'a*—Suppression of the menstruation.
Anaërobes, *an-a'-er-obs*—Microörganisms which thrive best when deprived of oxygen.
Analgesics, *an-al-je'-siks*—Medicines used to allay pain.
Anaphrodisiacs, *an-af-ro-diz'-e-aks*—Medicines used to allay sexual feeling.
Anaphylaxis, *an-ah-fil-ak'-sis*—A severe manifestation of increased susceptibility to a foreign protein when introduced some time after a primary injection.
Anemia, *an-e'-me-ah*—A deficiency of coloring matter (hemoglobin) of the blood.
Anesthetics, *an-es-thet'-iks*—Medicines used to destroy sensation.
Angina Pectoris, *an'-jin-ah pec'-tor-is*—A form of heart disease, usually accompanied with severe pain in the cardiac region; a sense of oppression.
Angioneurotic, *an-je-o-nu-rot'-ik*—Due to disease or injury to vasomotor nerves or center.
Anodynes, *an'-o-dins*—Medicines used to allay pain.
Antacids, *ant-as'-ids*—Medicines used to neutralize acidity.
Anthelmintics, *an-thel-min'-tiks*—Medicines used to get rid of intestinal parasites.
Antibody, *an'-ti-bod-y*—A substance in blood serum or body fluids which destroys microorganisms, neutralizes toxins, or otherwise counteracts antigens.
Antigen, *an'-te-jen*—In general, any product capable of stimulating the formation of antibodies.
Antihidrotics, *an-te-hi-drot'-iks*—Drugs used to stop sweating.
Antiperiodics, *an-te-pe-re-od'-iks*—Medicines used for the relief of malarial fevers.
Antipyretics, *an-te-pi-rĕt'-iks*—Medicines used to reduce temperature in fevers.
Antiseptics, *an-te-sep'-tiks*—Substances which prevent the development of bacteria.
Antispasmodics, *an-te-spaz-mŏd'iks*—Medicines which prevent or check fermentative processes in the digestive tract.
Aperients, *ah-pe'-re-ents*—Mild cathartics.
Aphrodisiacs, *af-ro-diz'-e-aks*—Substances used to increase sexual feeling.
Apoplexy, *ap'-o-pleks-e*—Paralysis from rupture of a cerebral vessel.
Aromatic Bitters, *ar-o-mat'-ik bit'-erz*—Medicines which unite the properties of the aromatics and the simple bitters.
Aromatics, *ar-o-mat'-iks*—Condiments or spicy, stimulating drugs.
Arteriosclerosis, *ar-te'-ri-o-skle-ro'-sis*—Hardening of the arterial walls.
Arthritis, *ar-thri'-tis*—Inflammation of the joints.
Asthma, *az'-mah*—A disease of respiration, characterized by difficult breathing, cough, etc.
Astringents, *as-trin'-gents*—Medicines used to contract organic tissue.
Atopy, *at'-o-pi*—Literally, a strange disease. A general term referring to conditions of protein sensitivity.

[1] This list is limited to the medical terms employed in this book in describing the uses of drugs.

Attenuate, *at-ten′-u-at*—Lowering of the virulence of microbes so that they can be safely used as a vaccine to confer immunity.
Bacillus, *bas-il′-us* (pl. *bacilli*)—Rod-shaped or elongated bacteria.
Bacteriolysins, *bak-te-ri-o-li′-sins*—Antibodies which destroy bacteria through a digestive or dissolving action.
Bacteriotropins, *bak-te-ri-o-tro′-pins*—Antibodies which make invading bacteria more amenable to phagocytosis.
Bitters, *bit′-erz*—Medicines having a bitter taste and the power to improve appetite, and impart tone to the digestive organs.
Botulism, *bot′-u-lizm*—A type of food poisoning caused by a toxin produced by B. Botulinus.
Bouillon, *boo-e-yon′*—A culture medium for bacteria made from lean beef, peptone, salt and normal sodium hydrate in fixed proportions.
Bright's Disease, *brits′ dis-ēz′*—A rather vague term applied to various diseases of the kidney.
Bronchitis, *bron-ki′-tis*—Inflammation of the bronchial tubes.
Bronchus, *brong′-kus* (pl. *bronchi*)—One of the two main branches of the trachea or windpipe.
Calculus, *kal′-ku-lus*—A stone-like concretion formed in the body.
Cancer, *kan′-ser*—A malignant form of tumor.
Carbuncle, *kar′-bunk-kel*—Circumscribed inflammation of the subcutaneous tissues, similar to a boil, but more extensive and severe.
Cardiac depressants, *kar′-de-ak de-pres′-ants*—Medicines used to lower the heart's action.
Cardiac stimulants, *kar′-de-ak stim′-u-lants*—Medicines used to increase the heart's action.
Carminatives, *kar-min′-at-ivs*—Medicines used to expel flatus (intestinal gas).
Catarrh, *kat-ar′*—Inflammation of a mucous membrane.
Catarrhal, *kat-ar′-al*—Relating to or affected with catarrh or inflammation of a mucous membrane.
Cathartics, *kath-ar′-tiks*—Drugs used to stimulate the movement of the bowels.
Caustics, *kaws′-tiks*—Medicines used to destroy living tissues.
Cerebrospinal, *ser-e-bro-spi′-nal*—Relating to the brain and the spinal cord.
Chalybeates, *ka-lib′-e-āts*—Ferruginous hematinics.
Chlorosis, *klo-ro′-sis*—A form of anemia most common in young women.
Cholagogues, *kol′-a-gogs*—Medicines which promote a flow of bile.
Cholera, *col′-er-ah*—A disease characterized by severe diarrhea, cramps, and prostration. The true *Cholera Asiatica* is caused by a specific germ. The terms *cholera morbus* and *cholera nostras* are applied to any severe diarrhea.
Chorea, *ko-re′-ah* (St. Vitus' Dance)—Involuntary muscular twitching.
Coagulability, *ko-ag-u-la-bil′-i-ti*—The capability of clotting or tendency to clot.
Colic, *kol′-ik*—Spasmodic pain in the abdomen.
Collapse, *kol-aps′*—Marked depression of the vital activities of the body, especially of the circulation.
Complement, *kom′-ple-ment*—A substance in the blood and normal serum resembling a ferment. Acts with the amboceptor (antibody) in causing lysis.
Conjunctivitis, *kon-jungk-tiv-i′-tis*—Inflammation of the mucous membrane of the eye.
Convulsion, *kon-vul′-shun*—Violent abnormal contraction of the muscles; a severe spasm.
Correctives, *ko-rek′-tivs*—Medicines used to correct, or render more pleasant, the action of other remedies, especially purgatives.
Coryza, *kor-i′-zah*—Catarrhal inflammation of the nose.
Counterirritants, *koun′-tĕr-ĭr′-i-tănts*—Drugs which relieve internal disorders by causing external inflammation.
Cycloplegic, *si′-klo-plē′-jik*—Destroying the power of the eye to focus on near objects.
Cystic, *sist′-ik*—Referring to the urinary bladder or gall bladder.
Cystitis, *sis-ti′-tis*—Inflammation of the urinary bladder.
Delirifacients, *de-lir′i-fā′-shĕnts*—Drugs causing delirium.
Delirium tremens, *de-lir-e-um trēmĕnz*—Mental aberration due to alcoholic poisoning.
Demulcents, *de-mul′-sents*—Mucilaginous substances used to soothe and protect irritated mucous membranes or other tissues.
Deodorants, *de-o′-dor-ants*—Substances which destroy or hide offensive odors.
Depilatories, *de-pil′-at-o-res*—Substances used to remove hair.
Depressants, *de-pres′-ants*—Drugs that lower function.
Detergents, *de-ter′-jents*—Medicines used to cleanse.
Detritus, *de-tri′-tus*—The remains of any broken-down tissue.
Diabetes insipidus, *di-ab-e′-tez in-sip′-i-dus*—A disease characterized by an excessive flow of urine.
Diabetes mellitus, *di-ab-e′-tez me-li′-tus*—A disease characterized by an excessive flow of urine containing sugar.
Diaphoretics, *di-af-or-et′-iks*—Medicines which produce sweating.

Diarrhea, *di-ar-e'-ah*—Excessive looseness of bowels.
Digestants, *di-jes'-tants*—Ferments and acids which have power of aiding in the digestion of food.
Diluents, *dil'-u-ents*—Medicines which dilute.
Discutients, *dis-ku'-shents*—Substances which aid in removing swellings.
Disinfectants, *dis-in-fek'-tants*—Substances which combat germs and the noxious properties of decaying organic matter.
Diuretics, *di-u-ret'-iks*—Medicines which increase the secretion of urine.
Dropsy, *drop'si*—An accumulation of fluid in the subcutaneous tissues.
Dysentery, *dis'-en-ter-e*—An infectious inflammation of the lower bowel characterized by bloody evacuations.
Dysmenorrhea, *dis-men-or-e'-ah*—Painful or irregular menstruation.
Dyspepsia, *dis-pep'-se-ah*—Indigestion.
Ecbolics, *ek-bol'-iks*—Medicines which produce contraction of the uterus.
Eclampsia, *ek-lamp'-se-ah*—A convulsive or epileptiform seizure, especially one in which consciousness is not lost.
Eczema, *ĕk'-zē-ma*—An inflammatory disease of the skin with exudation of lymph.
Edema, *e-de'-mah*—Swelling due to accumulation of watery fluid in lymph spaces of tissues
Embrocations, *em-bro-ka'-shuns*—Agents applied externally.
Emetics, *e-met'-iks*—Medicines which cause vomiting.
Emmenagogues, *em-en'-ag-ogs*—Medicines which stimulate menstruation.
Emollients, *e-mol'-yents*—Substances used to soften and protect tissues.
Empyema, *em-pi-e'-mah*—Pus in the pleural cavity.
Endermics, *en-der'-miks*—Relating to the administering of medicines through the skin by rubbing.
Endocarditis, *en-do-kar-di'-tis*—Inflammation of the lining membrane of the heart.
Endometritis, *en-do-me-tri'-tis*—Inflammation of the lining membrane of the uterus.
Enteric fever, *en-ter'-ik fe'-ver*—Typhoid fever.
Enuresis, *en-u-re'-sis*—Incontinence of urine.
Epididymitis, *ep-e-did-im-i'-tis*—Inflammation of the epididymis or excretory duct of the testis.
Epilepsy, *ep'-il-ep-se*—A nervous disease characterized by loss of consciousness, usually accompanied by convulsions, spasms, and foaming at the mouth.
Epispastics, *ep-i-spas'-tiks*—Blistering agents.
Erysipelas, *er-is-ip'-el-as*—An acute specific inflammation of skin and subcutaneous tissues, accompanied by fever and constitutional disturbances.
Erythema, *er-ith-e'-mah*—A superficial rash or redness of the skin.
Escharotics, *es-kar-ot'-iks*—Substances used to destroy pathologic tissue.
Evacuants, *e-vak'-u-ants*—Medicines which evacuate; applied chiefly to purgatives.
Excision, *ek-sizh'-un*—In surgery, any operative removal.
Excitants, *ek-si'-tants*—Drugs which increase functional activity.
Expectorants, *eks-pek'-tō-rants*—Agents used in the treatment of inflammations of the bronchial tract.
Febrifuges, *feb'-rif-ujs*—Medicines which dissipate fever.
Fibrous, *fi'-brus*—Composed of fibers, characteristic of connective tissue.
Flatulence, *flăt'-ū-lĕns*—The presence of gas in the digestive canal.
Focus, *fo'-kus* (pl. *foci*)—The center or starting point of a disease process.
Galactagogues, *gal-ak'-tag-ogs*—Medicines which increase the flow of milk.
Gangrene, *gang'-grēn*—Mortification or death of soft tissue.
Gastritis, *gas-tri'-tis*—Inflammation of the stomach.
Gastro-intestinal—Relating to both the stomach and the intestine.
Germicides, *jer'-mis-īds*—Agents which kill disease germs.
Globulin, *glob'-u-lin*—A protein substance of which several varieties are present in the blood.
Gluteal, *glu'-te-al*—Relating to the muscles of the buttocks.
Glycosuria, *gli-ko-su'-re-ah*—Presence of sugar in the urine.
Gout, *gowt*—A disease associated with joint inflammation, swelling, excessive uric acid in the blood, etc.
Hay fever—A catarrhal inflammation of respiratory mucous membranes due to pollens of certain plants.
Hematinics, *hem-at-in'-iks*—Agents which improve the quality of the blood.
Hemolytic, *hem-o-lit'-ik*—Destructive to blood cells.
Hemophilia, *hem-o-fil'-e-ah*—A tendency to profound hemorrhage due to a defect in coagulating power of the blood.
Hemorrhage, *hem'-or-āj*—A flow of blood from the vessels.
Hemorrhoids, *hĕm'-ŏ-roids*—Piles; small blood tumors at the anal orifice.
Hemostatics, *hem-o-stat'-iks*—Medicines which arrest hemorrhages.

Hydragogs, *hi'-dra-gogs*—Purgatives which cause profuse watery discharges.
Hydrophobia, *hi-dro-fo'-be-ah*—Rabies in man.
Hyperemia, *hi-per-e'-me-ah*—Congestion or excessive amount of blood in a part.
Hypnotics, *hip-not'-iks*—Medicines which cause sleep.
Hypochondriasis, *hi-po-kon-dri'-as-is*—Extreme depression, with morbid anxiety regarding the health.
Hysteria, *his-te'-re-ah*—Functional disturbance of nervous system.
Incision, *in-sizh'-un*—In surgery, the act of cutting into.
Infiltration, *in-fil-tra'-shun*—The permeation or penetration of a substance, cell or tissue by gas, fluid or dissolved matter.
Insecticides, *in-sek'-tis-īds*—Preparations for destroying insects.
Insomnia, *in-som'-ne-ah*—Inability to sleep.
Intradermal, *in-trah-der'-mal*—Intracutaneous or between the layers of the skin.
Intramuscular, *in-trah-mus'-ku-lar*—Within the muscles.
Intrascapular, *in-trah-scap'-u-lar*—Between the shoulder blades or scapulæ.
Intraspinal, *in-trah-spi'-nal*—Between spines. Refers to method of inserting needle between spines of adjacent vertebræ in order to make injection into or withdraw fluid from the spinal canal.
Intravenous, *in-trah-ve'-nus*—Within a vein.
Inunction, *in-ungk'-shun*—The rubbing of medicines into the skin.
Jaundice, *jawn'-dis*—A yellow coloration of the skin due to the absorption of bile into the blood.
Laryngitis, *lar-in-ji'-tis*—Inflammation of the larynx.
Laxatives, *laks'-at-ivs*—Mild cathartics.
Lesion, *le'-zhun*—A more or less circumscribed pathological change in tissues, due to injury or disease.
Leucocytes, *lu'-ko-sīts*—White blood cells.
Leukemia, *lu-ke'-me-ah*—A disease with a marked increase in the number of leucocytes in the blood.
Local Anesthetics, *lo'-kal an-es-thet'-iks*—Medicines which, when applied locally, destroy sensations.
Locomotor Ataxia, *lo'-ko-mo'-tor a-tak'-si-a*—A disease of the posterior columns of the spinal cord, marked by severe pains, incoördination, disturbances of sensations, etc.
Lumbago, *lum-ba'-go*—Pain in the loins.
Lumbar Puncture—The puncture into the spinal canal made in the lower region of the spine about level with the crests of the hip bones.
Lymph, *limf*—A clear fluid circulating in lymph spaces or lymphatic vessels of the body. Also smallpox vaccine lymph.
Lysins, *li'-sins*—A specific antibody which destroys cells and tissues.
Malaise, *mal-az'*—Feeling of general discomfort and uneasiness.
Malaria, *mal-a'-re-ah*—An infectious disease caused by a parasite in the blood.
Meningitis, *men-in-ji'-tis*—Inflammation of the membranes of the brain and spinal cord.
Menorrhagia, *men-or-a'-je-ah*—Excessive menstrual flow.
Microparasites, *mi-kro-par'-a-sits*—Bacterial and protozoön parasites too small to be seen with the unaided eye.
Mydriatics, *mid-re-at'-iks*—Agents which cause dilatation of the pupil.
Myeloma, *mi'-loma*—A tumor of medullary substances.
Myotics, *mi-ot'-iks*—Agents which contract the pupil.
Narcotics, *nar-kot'-iks*—Drugs which stupefy.
Nausea, *naw'-se-ah*—A sensation of sickness at the stomach with a desire to vomit.
Necrotic, *nek-rot'-ik*—Relating to necrosis or local degeneration and death of cells or tissues.
Nephritis, *nef-ri'-tis*—Inflammation of the kidney.
Neuralgia, *nu-ral'-je-ah*—Any painful condition not due to organic disease.
Neurasthenia, *nu-ras-the'-ne-ah*—Exhaustion of nerve force.
Neuritis, *nu-ri'-tis*—Inflammation of a nerve trunk.
Neurotic, *nu-rot'-ik*—A drug affecting the nervous system, or a person affected with nervous disorder.
Nutrients, *nu'-tre-ents*—Nutritious substances or foods.
Obesity, *o-bes'-it-e*—Fatness.
Ophthalmia, *off-thal'-me-ah*—Inflammation of the mucous membrane of the eye.
Opsonins, *op'-so-nins*—Antibodies which promote phagocytosis or the destruction of invading organisms by the white blood cells.
Oxytocics, *oks-e-tos'-iks*—Medicines which stimulate uterine contractions.
Palliatives, *pal'-e-a-tivs*—Agents which relieve but do not cure.
Papule, *pap'-ul*—A small circumscribed elevation of the skin containing no fluid.
Paralysis, *par-al'-is-is*—Complete loss of functional power, especially of muscles.

Parasiticides, *par-as-it'-is-ids*—Agents which inhibit the growth of or kill parasites on the body.
Paratyphoid, *par-a-ti'-foid*—A form of typhoid fever due to an organism closely related to the true Bacillus typhosus.
Parenteral, *par-en'-ter-al*—Introduction of substances into the body in some way other than by the intestinal tract.
Pathogenic, *path-o-jen'-ik*—Producing or causing disease.
Pericarditis, *per-e-kar-di'-tis*—Inflammation of the membranous sac around the heart.
Peristalsis, *per-is-tal'-sis*—The muscular movement of the bowels.
Peritonitis, *per-it-on-i'-tis*—Inflammation of the membrane lining the abdomen.
Phagocytes, *fag'-o-sīts*—White blood corpuscles which possess the property of ingesting and disposing of bacterial cells and foreign particles.
Phagocytosis, *fag-o-si-to'-sis*—The destruction of microbes by the action of phagocytes or cells possessing the property of absorbing.
Pharyngitis, *far-in-ji'-tis*—Inflammation of the pharynx.
Phthisis, *thi-sis, ti'-sis*—Tuberculosis of the lungs, commonly called consumption.
Placebo, *plas-e'-bo*—An inert drug used to satisfy patients.
Plague, *plag*—An acute infectious and epidemic disease due to the Bacillus Pestis.
Plasma, *plaz'-mah*—Fluid portion of the circulating blood and distinguished from serum obtained after coagulation.
Pleurisy, *plu'-ris-e*—Inflammation of the serous membrane covering the lungs.
Polyneuritis, *pol-e-nu-ri'-tis*—An inflammation affecting several nerves.
Polyvalent, *pol-iv'-al-ent*—Applied to serums containing antibodies for several strains of the same species of microörganism or to bacterial vaccines containing several strains of the same species.
Post-abortal, *post ab-ort'-al*—Following abortion.
Precipitins, *pre-sip'-i-tins*—Antibodies which precipitate bacteria of foreign substances.
Prophylactics, *pro-fil-ak'-tiks*—Medicines which prevent the development of disease.
Protectives, *pro-tek'tivs*—Medicines which mechanically protect a part when applied to it
Pruritis, *pru-ri'-tus*—An intense itching.
Pseudopods, *su'-do-pods*—An irregular process or protrusion resembling those of an amœba put forth for locomotion.
Psoriasis, *so-ri'-as-is*—A chronic inflammatory skin disease with scale formation.
Puerperal, *pu-er'-pe-ral*—Pertaining to childbirth.
Purgatives, *pur'-ga-tivs*—Medicines which produce copious discharges from the bowels.
Pustule, *pus'-tul*—Small circumscribed elevation of the skin containing pus.
Pyelitis, *pi-el-i'-tis*—Inflammation of the pelvis of the kidney.
Pyelography, *pi-log'-rah-fe*—X-ray treatment of a renal pelvis and ureter which have been filled with a silver salt solution.
Refrigerants, *re-frij'-er-ants*—Medicines which lessen the bodily temperature.
Restoratives, *re-stor'-a-tivs*—Medicines used to combat depression.
Rheumatism, *rum'-at-izm*—Applied to conditions characterized by pains of the muscles, joints and fibrous tissues.
Rhinitis, *ri-ni'-tis*—Inflammation of the nasal mucous membranes.
Rubefacients, *ru-be-fa'-se-ents*—Medicines which cause irritation and redness of the skin.
Sarcoma, *sar-ko'-mah*—A malignant form of tumor.
Scabies, *ska'-be-ēz*—Itch, a contagious, parasitic skin disease.
Sciatica, *si-at'-ik-ah*—Neuralgia of the sciatic nerve.
Scrofula, *skrof'-u-lah*—A constitutional condition with glandular tumors and a tuberculous tendency.
Scurvy, *skur'vi*—Diseased condition shown by hemorrhages into the skin, due to deficient or improper diet.
Sedatives, *sed'-at-ivs*—Medicines which allay irritability of an organ or nerve center.
Septic, *sep'-tik*—Relating to the presence of various pus forming or other pathogenic bacteria or their products.
Septicemia, *sep-tis-e'-me-ah*—Presence of microörganisms or toxins in the circulating blood.
Sequela, *se'-kwel-ah* (pl. *sequellæ*)—Morbid condition following or resulting from another disease.
Shock, *shok*—Profound depression resulting from severe injury, emotional disturbances, or operation.
Sialogogues, *si-al'-a-gogs*—Medicines which increase the secretion of saliva.
Somnifacients, *som-nif-a'-she-ents*—Drugs which produce sleep.
Soporifics, *so-por-if'-iks*—Medicines which produce sleep.
Spasm, *spazm*—Abnormal contraction of a muscle, or a group of muscles.
Specifics, *spe-sif'-iks*—Medicines which have a direct curative influence on certain individual diseases.

Sternutatories, *ster-nu'-ta-to-res*—Medicines which produce sneezing when applied to the nasal mucous membrane.
Stimulants, *stim'-u-lants*—Medicines which increase functional activity.
Stomachics, *stom-ak'-iks*—Stimulants to the stomach.
Stomatitis, *sto-mat-i'-tis*—Inflammation of the mouth.
Styptics, *stip'-tiks*—Agents which arrest bleeding by their local application.
Sudorifics, *su-dor-if'-iks*—Medicines which produce sweating.
Sycosis, *si-ko'-sis*—An inflammation of the hair follicles.
Syncope, *sin'-ko-pe*—Temporary failure of circulation; fainting.
Teniacides, *te'-ne-as-ids*—Medicines which kill the tapeworm.
Tonics, *ton'-iks*—Medicines which permanently increase the systemic tone by stimulating nutrition. This term is frequently misapplied to stimulants, especially the stomachics.
Trypanosomiasis, *tri-pan-o-so-mi'-as-is*—A diseased condition due to infection of a protozoan parasitic organism, commonly called *African Sleeping Sickness.*
Tuberculosis, *tu-bur-ku-lo'-sis*—A disease caused by the tubercle bacillus.
Ulcers, *ul'-sers*—Open sores on external or internal surfaces of the body with secretion of pus.
Uremia, *u-re'-mi-a*—Toxic condition of the blood from accumulation of substances normally excreted by the kidneys.
Urethritis, *u-re-thri'-tis*—Inflammation of the urethra.
Urticaria, *ur'-ti-ka'ri-ă*—Nettle rash; an ephemeral skin eruption with itching.
Vaccinia, *vak-sin'-e-ah*—Cowpox or eruptive disease occurring in cattle, similar to smallpox in man but milder. Inoculation with the virus confers immunity to smallpox.
Vaginitis, *vaj-in-i'-tis*—Inflammation of the vagina.
Vermicides, *ver'-mis-īds*—Medicines which kill intestinal worms
Vesicant, *ves'-ik-ant*—An agent producing a blister.
Vesicles, *ves'-ik-ls*—Small circumscribed elevations of the skin containing non-purulent fluid.
Virus, *vi'-rus*—The specific microörganism or poison of an infectious disease.
Wheal, *hwel*—A circumscribed elevation of the skin of varying shapes with white or pinkish surface and surrounded by a pink area.
Xerophthalmia, *zer-off-thal'-me-ah*—A dry and thickened condition of the conjunctiva.

NAMES AND ADDRESSES OF MANUFACTURERS

In previous editions of this book, apparatus and preparations were frequently illustrated or referred to without giving the names of manufacturers, with the result that many letters were received asking the sources of supply. The attempt is being made in this edition to remedy this deficiency and where apparatus is illustrated or preparations listed the manufacturer is being named. To make this information more complete the following list of names and addresses is appended solely for information.

Abbott Laboratories	Chicago, Ill.
Abbe Engineering Company, Broadway and Ann Streets	New York, N. Y.
Alsop Engineering Company, 47 West 63rd Street	New York, N. Y.
American Antiformum Company	New York, N. Y.
Arlington Chemical Company	Yonkers, N. Y.
Armour and Company	Chicago, Ill.
Arnold Electric Company	Racine, Wis.
Astier, P., Laboratories (George J. Wallau Inc.)	New York, N. Y.
Bayer Company	Rensselaer, N. Y.
B. B. Culture Laboratory, Inc.	Yonkers, N. Y.
Barker, Herman	Somerville, Mass.
Barnes, A. C., Company	Philadelphia, Pa.
Battle Creek Food Company	Battle Creek, Mich.
Bethlehem Laboratories	Bethlehem, Pa.
Bilhuber, E., Inc.	New York, N. Y.
Borcherdt Malt Extract Company	Chicago, Ill.
Brady, Geo. W., and Company	Chicago, Ill.
Britt, Loeffler and Weil	New York, N. Y.
Burroughs Adding Machine Company	Detroit, Mich.
Burroughs Wellcome and Company	London, Eng.
Calco Chemical Company	Bound Brook, N. J.
Central Scientific Company	Chicago, Ill.
Cereo Company	Tappan, N. Y.
Cheplin Biological Laboratories, Inc.	Syracuse, N. Y.
Chicago Dietetic Supply House	Chicago, Ill.
Chinosol Company	New York, N. Y.
Ciba Company, Inc.	New York, N. Y.
Coleman and Bell Company	Norwood, Ohio.
Coleman Laboratories	Wheeling, W. Va.
Connaught Laboratories, University of Toronto	Toronto, Canada
Cummings, W. L., Chemical Company	Lansdowne, Pa.
Cutter Laboratory	Berkeley, Calif.
Davis and Geck, Inc.	Brooklyn, N. Y.
Deshell Laboratories, Inc.	Los Angeles, Calif.
Diarsenol Company, Inc.	Buffalo, N. Y.
Diaprotein Company	Columbus, Ohio
Druggists Appliance Mfg. Company	Port Richmond, N. Y.
Dry Milk Company	New York, N. Y.
Eastman Kodak Company	Rochester, N. Y.
Fairchild Bros. and Foster	New York, N. Y.
Fritsche Bros., Inc.	New York, N. Y.
General Chemical Company	New York, N. Y.
Gilliland Laboratories, Inc.	Marietta, Pa.
Gradwohl Laboratories	St. Louis, Mo.

Hart, E. J., and Company, Ltd. ..... New Orleans, La.
Heilkraft Medical Company ..... Boston, Mass.
Heyden Chemical Company of America ..... Garfield, N. J.
Hoffmann-LaRoche Chemical Works ..... New York, N. Y.
Hoos, Louis ..... Chicago, Ill.
Howard-Holt Company ..... Cedar Rapids, Iowa
Hynson, Westcott and Dunning ..... Baltimore, Md.

Intarvin Company, Inc. ..... Long Island City, N. Y.
Interstate Chemical Company, 23 East 26th Street ..... New York, N. Y.
Intra Products Company ..... Denver, Colo.

Jensen-Salsberg Laboratories, Inc. ..... Kansas City, Mo.
Johnson and Johnson ..... New Brunswick, N. J.

Kasanof, D. R., and Company, 25 West 42nd Street ..... New York, N. Y.

Lederle Antitoxin Laboratories ..... New York, N. Y.
Lehn and Fink, Inc. ..... New York, N. Y.
Leich, Chas., and Company ..... Evansville, Ind.
Lilly, Eli and Company ..... Indianapolis, Ind.
Lister Bros., Inc ..... New York, N. Y.
Lumiere, A., Laboratories ..... New York, N. Y.

McCourt Label Cabinet Company ..... Bradford, Pa.
McNeil, Robert ..... Philadelphia, Pa.
Mallinckrodt Chemical Works ..... St. Louis, Mo.
Maltbie Chemical Company ..... Newark, N. J.
Maltine Company ..... Brooklyn, N. Y.
Manhattan Eye Salve Company ..... Louisville, Ky.
Mead Johnson and Company ..... Evansville, Ind.
Meadows Chemical Company ..... New York, N. Y.
Medical Laboratories, Inc ..... New York, N. Y.
Merck and Company ..... New York, N. Y.
Merrell-Soule Company ..... Syracuse, N. Y.
Merrell, Wm. S., Company ..... Cincinnati, Ohio
Metz, H. A., Laboratories, Inc ..... New York, N. Y.
Modern Office Devices, Inc., 675 Hudson Street ..... New York, N. Y.
Monsanto Chemical Works ..... St. Louis, Mo.
Morgenstern and Company ..... New York, N. Y.
Mulford, H. K., Company ..... Philadelphia, Pa.

National Aniline and Chemical Company ..... New York, N. Y.
National Homogenizer Corporation ..... Frankfort, N. Y.
National Pathological Laboratories ..... Chicago, Ill.
National Pharmacy Company ..... Oakland, Calif.
National Radium Products Company ..... New York, N. Y.
New York Intravenous Laboratory ..... New York, N. Y.
New York Quinine and Chemical Works ..... New York, N. Y.
North, Horace ..... Brooklyn, N. Y.
Northwestern Steel and Iron Works ..... Eau Claire, Wis.
Norton, John, Company ..... Columbus, Ohio
Nutrivoid Diabetic Flour Company ..... New York, N. Y.

Ohio Chemical and Manufacturing Company ..... Cleveland, Ohio

Parke, Davis and Company ..... Detroit, Mich.
Parmele Pharmacal Company ..... New York, N. Y.
Pasteur Institute of St. Louis ..... St. Louis, Mo.
Patch, E. L., Company ..... Boston, Mass.
Pfandler Chemical Company ..... Rochester, N. Y.
Pitman-Moore Company ..... Indianapolis, Ind.
Powers-Weightman-Rosengarten Company ..... Philadelphia, Pa.
Pure Gluten Food Company ..... Brooklyn, N. Y.

Radium Chemical Company ..... Pittsburgh, Pa.
Radium Emanation Corporation ..... New York, N. Y.
Radium Limited, U. S. A. ..... New York, N. Y.

Read Machinery Company ..... York, Pa.
Reinschild Chemical Company ..... New York, N. Y.
Reynolds and Reynolds ..... Dayton, Ohio
Riedel and Company ..... New York, N. Y.
Roessler and Hasslacher Chemical Company ..... New York, N. Y.

Schering and Glatz, Inc. ..... New York, N. Y.
Schiefflin and Company ..... New York, N. Y.
Schultz, O'Neil Company ..... Minneapolis, Minn.
Scott, Henry L., and Company ..... Providence, R. I.
Seydel Manufacturing Company ..... Jersey City, N. J.
Sharpe and Dohme ..... Baltimore, Md.
Sherman, G. H. ..... Detroit, Mich.
Shriver, T., and Company ..... Harrison, N. J.
Squibb, E. R., and Sons ..... New York, N. Y.
Standard Oil Company (Indiana) ..... Chicago, Ill.
Stearns Frederick and Company ..... Detroit, Mich.
Straub, A. W., Company ..... Philadelphia, Pa.
Sullivan, James F., 829 N. 5th Street ..... Camden, N. J.
Synthetic Drug Company ..... Toronto, Canada

Takamine Laboratory, Inc ..... Clifton, N. J.
Tappan Zee Surgical Company ..... Nyack, N. Y.

United States Industrial Chemical Company ..... New York, N. Y.
United States Radium Corporation ..... New York, N. Y.
United States Standard Products Company ..... Woodworth, Wis.
United Synthetic Chemical Corporation ..... New York, N. Y.

Vallez Rotary Filters Company ..... Bay City, Mich.
Van Dyk, L. A. ..... New York, N. Y.
Vitalait Laboratory of California ..... Pasadena, Calif.

Wallace and Tiernan Company, 233 Broadway ..... New York, N. Y.
Wallau, George J., Inc ..... New York, N. Y.
Waukesha Health Products Company ..... Waukesha, Wis.
Welty Company ..... Chicago, Ill.
Werner Drug and Chemical Company ..... Cincinnati, Ohio
West Disinfecting Company ..... New York, N. Y.
Western Chemical Company, Inc. ..... Hutchinson, Minn.
White Chemical Company ..... Wilmington, N. C.
Wilson Laboratories ..... Chicago, Ill.
Winthrop Chemical Company, Inc. ..... New York, N. Y.

INDEX

HEAVY BLACK FIGURES INDICATE THE PAGES UPON WHICH WORKING PROCESSES OR STANDARDS WILL BE FOUND
